## (54) EDITING DEVICE

## (57)Abstract:

**PROBLEM TO BE SOLVED:** To perform nonlinear editing without deteriorating a transfer rate of a reproducing data even when a slow accessible storage device is used for housing material data and also the number of editing points is increased.

**SOLUTION:** At the time of deciding an editing point, a data adjacent to the editing point in the material data is copied from a material disk device 21 to a work disk device 22, and when the data adjacent to the editing point is to be reproduced, at the time of reproducing the edited data, first, the copied data in the work disk device 22 is read out to be the reproducing data, and also in the meantime, a data to be reproduced in the material disk device 21 is accessed, and after completion of this access, the read data from the theme disk device 21 becomes the reproducing data.

**CLAIMS**

---

[Claim(s)]

[Claim 1] In the edit equipment for performing non-linear editing of image data or voice data using the storage in which random access is possible It connects with the 2nd storage for storing the data near [ in the 1st storage in which the random access which stored material data is possible, and material data ] the editing point. In case an editing point is determined, the data near [ in material data ] the editing point are reproduced from the 1st storage to the 2nd storage. at the time of reproduction of the data after edit In case the data near the editing point are reproduced, while reading the data first reproduced by the 2nd storage and considering as reproduction data While having read the data reproduced by the 2nd storage, access to the data which should be reproduced in the 1st storage is performed. Edit equipment characterized by having the control means which change reproduction data from the data read from the 2nd storage to the data read from the 1st storage after this access was completed.

[Claim 2] The aforementioned control means are edit equipment according to claim 1 characterized by packing an interval and recording the data near the editing point on the 2nd storage according to the turn that the data near the editing point are reproduced in case the data near [ in material data ] the editing point are reproduced from the 1st storage to the 2nd storage.

## DETAILED DESCRIPTION

## [Detailed Description of the Invention]

[0001]

[The technical field to which invention belongs] this invention relates to the edit equipment for performing non-linear editing of image data or voice data using the storage in which random access is possible.

[0002]

[Description of the Prior Art] The edit method conventionally performed when editing image data is the method of reproducing only the required portion of a material record medium and reproducing this one by one to another record medium. Generally, such an edit method is called linear editing. On the other hand, the edit method called non-linear editing using the storage in which random access, such as a hard disk drive unit, is possible is being circulated in recent years. In this non-linear editing, by a certain method, the position where the required image in a material record medium is recorded is determined, and this is memorized as editing point information, such as carrying out rapid-traverse reproduction of the material record medium in which random access is possible first. And at the time of reproduction, a desired image program can be acquired by performing random access to a material record medium according to editing point information.

[0003] In linear editing, in order to perform duplicate processing, the working hours which edit takes become longer than the reproduction time of the completed image program at least. On the other hand, in non-linear editing, it is rapid-traverse reproduction etc., and since what is necessary is just to determine even an editing point, the time which an editing task takes can be shortened. Thus, in non-linear editing, efficient work can be done in a short time taking advantage of the advantage of the storage in which random access is possible.

[0004]

[Problem(s) to be Solved by the Invention] By the way, generally in non-linear editing, the disk unit is used as storage in which random access is possible. However, such a disk unit is not the reason in which perfect random access is possible, and requires the time for seeking a head or performing rotational delay on the occasion of access. Especially, in an optical disk unit etc., generally the seek time and rotational delay are large, and these influences cannot be disregarded. For example, in non-linear editing, supposing it connects a different portion in a material record medium for every frame, when reproducing this, seek operation will occur for every frame. Thus, since one seeking must be performed whenever it reads to data of only one frame, the average transfer rate of read-out falls remarkably. If this average transfer rate is less than a required value, a reproduction image will become way piece \*\*\*\*\*. Thus, in the edit equipment which performs non-linear editing, in order to reproduce reproduction data at the transfer rate more than fixed continuously, the number of the editing points in a certain section will be restricted, and it depends for this limiting value on the access time of the storage in which random access is possible.

[0005] Therefore, generally as storage in which the random access in non-linear editing is possible, the quick hard disk drive unit of access etc. is more desirable than the late optical disk unit of access etc. However, on the other hand, an optical disk unit has the advantage of being suitable for recording material data, when using the image recorded outdoors, for example as material data, since the record medium is generally removable. In addition, although the advantage of the both sides of an optical disk unit and a hard disk can be harnessed once it reproduces the material data recorded with the optical disk unit to a hard disk, considering the time of a duplicate, the merit of non-linear editing that it can edit will be lost for a short time.

[0006] this invention was made in view of this trouble, and even if the number of the purpose of editing points increases in material data storage, using the late storage of access, it is to offer the edit equipment which enabled it to perform non-linear editing, without reducing a reproduction data transfer rate.

[0007]

[Means for Solving the Problem] In the edit equipment for the edit equipment of this invention performing non-linear editing of image data or voice data using the storage in which random access is possible. It connects with the 2nd storage for storing the data near [in the 1st storage in which the random access which stored material data is possible, and material data] the editing point. In case an editing point is determined, the data near [in material data] the editing point are reproduced from the 1st storage to the 2nd storage. at the time of reproduction of the data after edit. In case the data near the editing point are reproduced, while reading the data first reproduced by the 2nd storage and considering as reproduction data. While having read the data reproduced by the 2nd storage, access to the data which should be reproduced in the 1st storage is performed. After this access is completed, it has the control means which change reproduction data from the data read from the 2nd storage to the data read from the

1st storage.

[0008] With this edit equipment, in case an editing point is determined, the data near [ in material data ] the editing point are reproduced by the 2nd storage from the 1st storage by control means. And at the time of reproduction of the data after edit, by control means, in case the data near the editing point are reproduced. The data reproduced by the 2nd storage of introduction are read, and it considers as reproduction data. While the data reproduced by the 2nd storage are read, access to the data which should be reproduced in the 1st storage is performed. After this access is completed, reproduction data are changed from the data read from the 2nd storage to the data read from the 1st storage.

[0009]

[Embodiments of the Invention] Hereafter, the gestalt of operation of this invention is explained in detail with reference to a drawing.

[0010] Drawing 1 is the block diagram showing the structure of a system containing the edit equipment concerning the gestalt of operation of the 1st of this invention. The disk unit 21 for materials as the 1st storage in which the random access which this system was connected to the edit equipment 10 concerning the gestalt of this operation and this edit equipment 10, and stored material data is possible. It connected with edit equipment 10, and it connected with the disk unit 22 for work and the edit equipment 10 as the 2nd storage for storing the data near [ in material data ] the editing point, and has the monitor 23 for displaying a picture. It connected with the disk unit 21 for materials, the disk unit 22 for work, and the monitor 23, and edit equipment 10 is equipped with the control unit 13 as control means which control these while it connects with the editing point information storage device 12, and the user interface 11 and the editing point information storage device 12 for memorizing the information on the editing point in the user interface 11 and material data for performing operation of determining the editing point in material data and it controls these. Control information and data 31 are sent and received between a control unit 13, and the disk unit 21 for materials and the disk unit 22 for work, control information 32 is sent and received between a control unit 13 and a user interface 11, and the editing point information 33 is sent and received between a control unit 13 and the editing point information storage device 12. Moreover, a control unit 13 outputs the reproduction data 34 after edit.

[0011] The user interface 11 contains various kinds of switches, levers, etc. The editing point information recording device 12 is equipment for memorizing time codes, such as a start point of each cut, and an ending point, and consists of a hard disk, semiconductor memory, etc. The control unit 13 has CPU (central processing unit), ROM (read only memory) which stored the program which this CPU performs, and RAM (random access memory) used as a working area.

[0012] Both the disk unit 21 for materials and the disk unit 22 for work shall have the capacity to perform record and reproduction of image data or voice data, and the recorded data shall be managed by the time code. An optical disk unit is used as a disk unit 21 for materials, and a hard disk is used as a disk unit 22 for work.

[0013] The outline of operation of the edit equipment 10 applied to the gestalt of this operation here is explained. Here, it thinks taking the case of the case where use an optical disk unit as a disk unit 21 for materials, and a hard disk is used as a disk unit 22 for work. Since the lateness of access of the optical disk unit as a disk unit 21 for materials is covered, when reproducing material data to a hard disk beforehand, it is not necessary to reproduce all the material data to a hard disk. Namely, what is necessary is to reproduce only the data of the period which is equivalent to Taccs from a head, respectively in each cut to connect, if maximum of the time which seeking and rotational delay in an optical disk unit take is set to Taccs. If it sets, in this way, in the case of reproduction of the data after edit. The data read from the hard disk are used as reproduction data between Taccs(es) of the head of each cut. in the meantime After it performs access to the data which should be reproduced in an optical disk unit and the period of Taccs passes. The lateness of access of an optical disk unit is suppliable with changing so that the data which replaced with the data read from a hard disk, and were read from the optical disk unit may be used as reproduction data.

[0014] In order to realize above-mentioned processing, the procedure of reproducing the data of the period of Taccs from the head of each cut from an optical disk unit to a hard disk is required. by the way, a common optical disk unit — setting — Taccs — at most — it is number dozens to 100 m seconds. On the other hand, an editing-task company determines an editing point, looking at the picture near the editing point by rapid-traverse reproduction etc., after giving near aim, in case an editing point is determined. Since it is the work whose human being does such work, although one editing point is determined, even if short, it takes several seconds. Therefore, though the data of the period of Taccs are reproduced from the head of a cut from an optical disk unit to a hard disk when an editing point is determined, it can carry out abbreviation disregard in time for an editing-task company.

[0015] In case an editing-task company determines an editing point with the edit equipment 10 concerning the gestalt of this operation by the above idea using a user interface 11, a control unit 13 reproduces the data of the period of Taccs from the head of each cut from the disk unit 21 for materials (optical disk unit) to the disk unit 22 for work (hard disk) while making the editing point information storage device 12 memorize the information on an editing point. At the time for reproduction of the data after edit, moreover, a control unit 13. In case the data near the editing point are reproduced, while reading the data first reproduced by the disk unit 22 for work and considering as the reproduction data 34. After performing access to the data which should be reproduced in the disk unit 21 for materials in the meantime and completing this access, control which uses as the reproduction data 34 the data which replaced with the data read from the disk unit 22 for work, and were read from the disk unit 21 for materials is

performed.

[0016] Next, operation of the edit equipment 10 concerning the form of this operation is explained concretely. Here, the maximum Taccs of the access time of this optical disk unit is assumed to be 1 second using the optical disk unit as a disk unit 21 for materials. An optical disk unit is loaded with the optical disk with which material data were recorded. Drawing 3 (a) is a timing chart which shows the position of the cut in the data recorded on the optical disk as a record medium in the disk unit 21 for materials. Hereafter, as shown in drawing 3 (a), the case where edit which extracts cut (1) 41 and cut (2) 42, and connects from the data recorded on the optical disk is performed is considered. In addition, in drawing 3 (a), A1 and C1 express the start point of cut (1) 41, and an ending point, respectively, and A2 and C2 express the start point of cut (2) 42, and the ending point, respectively. Tcut1 expresses the time of cut (1) 41, and Tcut2 expresses the time of cut (2) 42. Moreover, B1 expresses the point after Taccs progress from A1, and B-2 expresses the point after Taccs progress from A2.

[0017] When extracting and connecting cut (1) 41 and cut (2) 42 as mentioned above, with the gestalt of this operation, the data of the portion (it is hereafter described as a head portion.) of the period of Taccs are reproduced from the head of each cut from the disk unit 21 for materials to the disk unit 22 for work. Drawing 3 (b) is a timing chart which shows the data recorded on the disk unit 22 for work. In this drawing 3 (b), a sign 51 expresses the head portion of a cut (1), and the sign 52 expresses the head portion of a cut (2). In the disk unit 22 for work, these head portions 51 and 52 pack an interval, and are recorded. Moreover, in drawing 3 (b), D1 expresses the point of a start of the head portion 51 of a cut (1), D2 expresses the point (it is the same as the point of an end of the head portion 51 of a cut (1).) of a start of the head portion 52 of a cut (2), and D3 expresses the point of an end of the head portion 52 of a cut (2).

[0018] Moreover, below, the time code of each point shown in drawing 3 (a) and (b) explains taking the case of the case where it is the value shown in drawing 4. In addition, with the notation of the time code shown in drawing 4, two digits divided by m, s, and f shall express a part, a second, and a frame, and may be 1 second at 30 frames, respectively.

[0019] Drawing 2 is the flow chart showing operation at the time of edit of the edit equipment 10 concerning the gestalt of this operation. At the time of this edit, a control unit 13 sets initial value of the cut number n to 1 as initial setting first. Moreover, although the copy place time code variable D used in order to show the points D1 and D2 in the disk unit 22 for work and — needs to point out the head of the suitable free area on the record medium in the disk unit 22 for work as initial value, it shall point out D1 point in drawing 3 (b), and sets it to D=00m00s00f here (Step S101). Next, a control unit 13 judges whether it is an edit end (Step S102), and, in an edit end, (Y) ends operation at the time of edit. In addition, directions of being an edit end are performed when an editing-task company operates a user interface 11.

[0020] When it is not an edit end (step S102:N) An editing-task company is operating a user interface 11, and minds a control unit 13. Publishing commands (control information), such as reproduction, a rapid traverse, and command delivery, to the disk unit 21 for materials, displaying the picture of material data on a monitor 23, and looking at this picture Cut (1) The point of A1 in the head position (a), i.e., drawing 3, of 41 is looked for, and a picture is stopped in the position. And an editing-task company operates start point determination by pushing the predetermined switch in a user interface 11 etc. Thereby, the input of the start point time code variable A is performed, and it is set up with A=A1 (Step S103). In response, as for a control unit 13, the time code in the disk unit 22 for work reproduces the data from A1 point [in / the section (a), i.e., drawing 3, from A to A+Taccs / in the time code in the disk unit 21 for materials] to B1 point from the point of D, i.e., D1 point in drawing 3 (b), to a field (Step S104). If the picture is displayed on a monitor 23 with the duplicate of data at this time, an editing-task company can check an editing point. Next, a control unit 13 saves the start point time code variable A and the copy place time code variable D to the field of A (n) in the editing point information storage device 12, and D (n), respectively (Step S105).

[0021] Next, an editing-task company is operating a user interface 11, looks for the ending point of cut (1) 41, i.e., C1 point, and operates ending point determination by pushing a switch etc. Thereby, the input of the ending point time code variable C is performed, and it is set up with C=C1 (Step S106). A control unit 13 saves this ending point time code variable C to the field of C (n) in the editing point information storage device 12 (Step S107). At this time, as shown in drawing 5, editing point information (A (1), C (1), D (1)) will be recorded on the editing point information storage device 12. Next, a control unit 13 increments the cut number n one time (Step S108), equips the next edit with it, and as D=D+Taccs, as (Step S109) and D point out the free area of the degree in the disk unit 22 for work, i.e., D2 point, it returns to Step S102.

[0022] And an editing-task company looks for and determines a start point A2 and the ending point C2 similarly about cut 2 by performing Step S103 or Step S109 again. Thereby, the start point time code variable A and the ending point time code variable C are set up with A=A2 and C=C2, respectively. As for a control unit 13, the time code in the disk unit 22 for work reproduces the data from A2 point [in / the section (a) i.e., drawing 3, from A to A+Taccs / in the time code in the disk unit 21 for materials] to B-2 point from the point of D, i.e., D2 point in drawing 3 (b), to a field. A control unit 13 saves each time code variables A, D, and C again to the field of A (n) in the editing point information storage device 12, D (n), and C (n), respectively. At this time, as shown in drawing 6, editing point information will be recorded on the editing point information storage device 12.

[0023] An editing-task company does in this way, and determines an editing point on after another, and the information is recorded on the editing point information storage device 12.

[0024] Drawing 7 is the flow chart showing operation at the time of the reproduction after edit of the edit equipment

10 concerning the gestalt of this operation. At the time of this reproduction, a control unit 13 sets initial value of the cut number  $n$  to 1 as initial setting first (Step S201). Next, a control unit 13 judges whether  $A(n)$  exists with reference to the editing point information storage device 12 (Step S202). When  $A(n)$  does not exist, (N) ends operation at the time of reproduction. When  $A(n)$  exists, a control unit 13 reads  $A(n)$ ,  $C(n)$ , and  $D(n)$  from the editing point information storage device 12, and (Y) sets up the time code variables  $A$ ,  $S$ ,  $C$ , and  $D$  with  $A=A(n)$ ,  $S=A(n)+Taccs$ ,  $C=C(n)$ , and  $D=D(n)$ , respectively. In addition, since it is  $n=1$ , they are  $A=A(1)$ ,  $S=A(1)+Taccs$ ,  $C=C(1)$ , and  $D=D(1)$  here. Next, as for a control unit 13, according to these time code variables, a time code [in / the disk unit 22 for work / for the data of the head portion of a cut (1)] starts read-out from the point of  $D$ , i.e.,  $D1$  point in drawing 3 (b), (Step S204). With it, to the disk unit 21 for materials, a control unit 13 publishes an instruction so that a time code may seek at the point of  $S$  (Step S205). Here,  $S$  points have pointed out the point after  $Taccs$ , i.e.,  $B1$  point in drawing 3 (a), from  $A1$  point. And after waiting (Step S206) and  $Taccs$  pass, only the time of  $Taccs$  ends read-out from the disk unit 22 for work (Step S207), and is changed from the disk unit 21 for materials which should already have completed seeking to read-out (Step S208). Then, a control unit 13 increments waiting (Step S209) and Variable  $n$  one time (Step S210), returns to Step S202, and moves from the time of  $C-S$  passing to regeneration of the next cut.

[0025] A control unit 13 sets up the time code variables  $A$ ,  $S$ ,  $C$ , and  $D$  with  $A=A(2)$ ,  $S=A(2)+Taccs$ ,  $C=C(2)$ , and  $D=D(2)$  with reference to the editing point information storage device 12, respectively. And a control unit 13 starts read-out according to these time code variables from  $D2$  point [in / the point of  $D$ , i.e., drawing 3 (b) / in a time code / in / the disk unit 22 for work / for the data of the head portion of a cut (2)]. With it, to the disk unit 21 for materials, a control unit 13 publishes an instruction so that a time code may seek at the point of  $S$ . Here,  $S$  points have pointed out the point after  $Taccs$ , i.e.,  $B-2$  point in drawing 3 (a), from  $A2$  point. And after  $Taccs$  passes, read-out from the disk unit 22 for work is ended, and it changes from the disk unit 21 for materials which should already have completed seeking to read-out.

[0026] Thus, at the time of reproduction, data without a way piece are reproducible with reference to the data of the editing point information storage device 12 by reading data from the disk unit 22 for work, and the disk unit 21 for materials by turns.

[0027] As explained above, in case an editing point is determined according to the edit equipment 10 concerning the gestalt of this operation. The data near [in material data] the editing point are reproduced from the disk unit 21 for materials to the disk unit 22 for work. at the time of reproduction of the data after edit. In case the data near the editing point are reproduced, while reading the data first reproduced by the disk unit 22 for work and considering as reproduction data. Access to the data which should be reproduced in the disk unit 21 for materials in the meantime is performed. Since it was made to use the data which replaced with the data read from the disk unit 22 for work, and were read from the disk unit 21 for materials as reproduction data after this access was completed. Even if the number of editing points increases in the disk unit 21 for materials, using the late storage of access, non-linear editing can be performed without reducing a reproduction data transfer rate. Therefore, as a disk unit 21 for materials, even if access is slow, storage with the merit that a record medium is removable or that it is cheap can be used. For example, it is realizable to carry out non-linear editing of the material data recorded with the camera on apparatus videocassette recorder using the optical disk and the magnetic tape as a record medium, and to send them out as it is.

[0028] Next, the edit equipment concerning the form of operation of the 2nd of this invention is explained. Depending on the cut to edit, the time may be shorter than  $Taccs$ . Drawing 8 (a) is a timing chart which shows the position of the cut in the data recorded on the disk unit 21 for materials, when it includes such a cut. In addition, in drawing 8 (a),  $A3$  and  $C3$  express the start point of cut (3) 43, and an ending point, respectively, and  $A4$  and  $C4$  express the start point of cut (4) 44, and the ending point, respectively.  $Tcut3$  expresses the time of cut (3) 43, and  $Tcut4$  expresses the time of cut (4) 44. Moreover,  $B3$  expresses the point after  $Taccs$  progress from  $A3$ , and  $B4$  expresses the point after  $Taccs$  progress from  $A4$ . Moreover, only  $Tcopied$  which mentions  $E4$  later from  $B4$  expresses the front point. In the example shown in drawing 8 (a), the time  $Tcut3$  of cut (3) 43 is shorter than  $Taccs$ .

[0029] The edit equipment concerning the gestalt of this operation is the example which enabled it to cope with it when above. The fundamental composition of the edit equipment concerning the gestalt of this operation is as having been shown in drawing 1 like the gestalt of the 1st operation.

[0030] Drawing 9 is the flow chart showing operation at the time of edit of the edit equipment concerning the gestalt of this operation. In this operation, first, as initial setting, a control unit 13 sets initial value of the cut number  $n$  to 1, and sets the copy place time code variable  $D$  to 00m00s00 f. Furthermore, a control unit 13 is the flag Small which shows whether the time of a cut is shorter than a predetermined reference value. Cut is set to 0 and the variable  $Tcopied$  which shows the sum total time of the cut reproduced as a cut shorter than  $Taccs$  within Time  $Taccs$  is set to 00m00s00 f (Step S301). Next, a control unit 13 judges whether it is an edit end (Step S302), and, in an edit end, (Y) ends operation at the time of edit.

[0031] When it is not an edit end (step S302:N), an editing-task company is operating a user interface 11, publishing commands (control information), such as reproduction, a rapid travels, and coma delivery, to the disk unit 21 for materials, displaying the picture of material data on a monitor 23, and looking at this picture through a control unit 13, looks for the head position of a cut ( $n$ ), and stops a picture in the position. And an editing-task company operates start point determination by pushing the predetermined switch in a user interface 11 etc. Thereby, the input of the start point time code variable  $A$  is performed (Step S303). Next, a control unit 13 is Flag Small. Cut judges whether it is 0 (Step S304). Flag Small When Cut is 0, a time code [in / the disk unit 22 for work / in a time

code / in / the disk unit 21 for materials / (Y) / in a control unit 13 ] reproduces the data of the section from A to A+Taccs to the field of D to D+Taccs (Step S305), and time codes A and D are saved to the field of A (n) in the editing point information storage device 12, and D (n), respectively (Step S306). On the other hand, it is Flag Small. When Cut is not 0 (step S304;N), from D+Tcopied, a time code [ in / the disk unit 22 for work / in the time code in the disk unit 21 for materials ] overwrites the field of D+Taccs, and reproduces the data of the section from A to A+Taccs-Tcopied (Step S307), and a control unit 13 overwrites and saves the value of A-Tcopied to the field of A (n) in the editing point information storage device 12 (Step S308).

[0032] If Step S306 or Step S308 is completed, an editing-task company is operating a user interface 11, will look for the ending point of a cut (n), and will operate ending point determination by pushing a switch etc. Thereby, the input of the ending point time code variable C is performed (Step S309). Next, a control unit 13 compares the time from the start point of a cut to an ending point, i.e., C-A, and Taccs-Tcopied, and C-A judges whether it is more than Taccs-Tcopied (Step S310). (Y) sets Variable Tcopied to 00m00s00 f while a control unit 13 sets Flag SmallCut to 0, when C-A is more than Taccs-Tcopied (Step S311). Next, a control unit 13 saves the ending point time code variable C to the field of C (n) in the editing point information storage device 12 (Step S312). Next, a control unit 13 increments the cut number n one time (Step S313), equips the next edit with it, and returns to (Step S314) and Step S302 as D=D+Taccs. On the other hand, when C-A is not more than Taccs-Tcopied (step S310;N), a control unit 13 is Flag Small. While setting Cut to 1, it newly returns to Step S302 by setting to Tcopied the value which added C-A to Tcopied (Step S315).

[0033] Here, after performing edit of a cut (1) as shown in drawing 3 (a), and a cut (2) to the material data recorded on the disk unit 21 for materials, as shown in drawing 8 (a), cut (3) 43 and cut (4) 44 are extracted, and the case where edit which connects is performed is considered. Drawing 8 (b) is a timing chart which shows the data recorded on the disk unit 22 for work at the time of this edit of cut (3) 43 and cut (4) 44. In drawing 8 (b), a sign 53 expresses a cut (3) and the sign 54 expresses the head portion of a cut (4). These cuts (3) In the disk unit 22 for work, the head portions 54 of 53 and a cut (4) pack an interval, and are recorded. Moreover, in drawing 8 (b), D3 expresses the point of a start of a cut (3), F4 expresses the point of a start of the head portion 54 of a cut (4), and D4 expresses the point of an end of the head portion 54 of a cut (4). Cut (3) The time Tcut3 of 53 is shorter than Taccs, and the time which doubled cut (3) 53 and the head portion 54 of a cut (4) serves as Taccs. Moreover, below, the time code of each point shown in drawing 8 (a) and (b) explains taking the case of the case where it is the value shown in drawing 10.

[0034] At the time of the edit about the cut (1) shown in introduction and drawing 3 (a), and a cut (2), it sets to the flow chart shown in drawing 9, and is Flag Small. Since Cut is set to 0 (step S304;Y) and C-A sets it more than Taccs-Tcopied (step S310;Y), operation at the time of edit becomes being the same as that of operation shown in drawing 2, and edit is performed as the gestalt of the 1st operation explained Next, in the case of the edit about a cut (3), they are n=3, and D= 00m02s00 f. An editing-task company looks for the head position of cut (3) 43, i.e., the point of A3, shown in drawing 8 (a), and operates start point determination by pushing the predetermined switch in a user interface 11 etc. Thereby, the start point time code variable A is set up with A=A3 (Step S303). this time - flag Small Cut - with 0 - it is (step S304;Y) - it is - as for a control unit 13, the time code in the disk unit 22 for work reproduces the data from A3 point [ in / the section from A to A+Taccs, i.e., drawing 8 (a) / in the time code in the disk unit 21 for materials ] to B3 point to the field of D to D+Taccs (Step S305) Under the present circumstances, although invalid data are reproduced after F4 in drawing 8 (b), this is not taken as a problem. A control unit 13 saves time codes A and D further to the field of A (3) in the editing point information storage device 12, and D (3), respectively (Step S306). At this time, as shown in drawing 11, editing point information will be recorded on the editing point information storage device 12.

[0035] Then, an editing-task company looks for the ending point, i.e., C3 point, of cut (3) 43 shown in drawing 8 (a), and operates ending point determination. Thereby, the ending point time code variable C is set up with C=C3. At this time, a control unit 13 compares the time from the start point of a cut to an ending point, i.e., C-A, and Taccs-Tcopied, and C-A judges whether it is more than Taccs-Tcopied (Step S310). Here, when C-A is more than Taccs-Tcopied, it is the same as the case of a cut (1) or a cut (2). However, in the cut (3) shown in drawing 8 (a), the time from A3 to C3 is smaller than Taccs. Moreover, Tcopied serves as 00m00s00 f at this time. Therefore, C-A becomes smaller than Taccs-Tcopied (step S310;N), and a control unit 13 is Flag Small. While setting Cut to 1, the value which added C-A to Tcopied is newly set to Tcopied (Step S315). At this time, since Tcopied is 00m00s00 f, it serves as Tcopied=C-A. Furthermore, a control unit 13 does not record the value of the point C, i.e., a time code variable, ending [ cut ] on the editing point information storage device 12 in this case. Moreover, n and a D value are not updated.

[0036] Next, an editing-task company looks for the head position of cut (4) 44, i.e., the point of A4, shown in drawing 8 (a), and operates start point determination by pushing the predetermined switch in a user interface 11 etc. Thereby, the start point time code variable A is set up with A=A4 (Step S303). Next, a control unit 13 is Flag Small. Cut is investigated (Step S304). after the ending point determination of a cut (3), and flag Small Cut is set as 1 (step S304;N) - it is - a control unit 13 The time code in the disk unit 21 for materials The section from A to A+Taccs-Tcopied. That is, from D+Tcopied, the time code in the disk unit 22 for work overwrites the field of D+Taccs, i.e., a field, from F4 point in drawing 8 (b), and reproduces the data from A4 point in drawing 8 (a) to E4 point (Step S307). Moreover, a control unit 13 overwrites the value of A-Tcopied to the field of A (n) in the editing point information storage device 12, and is saved (Step S308). Although information is recorded on the field of this time A (3) as already shown in drawing 11, it overwrites here and records on it.

[0037] Then, an editing-task company looks for the ending point, i.e., C4 point, of cut (4) 44 shown in drawing 8 (a), and operates ending point determination. Thereby, the ending point time code variable C is set up with  $C=C4$ . This time —  $C-A$  — more than  $T_{accs}-T_{copied}$  — it is (step S310;Y) — a control unit 13 — flag Small Variable  $T_{copied}$  is set to 00m00s00f while setting Cut to 0 (Step S311). Moreover, a control unit 13 saves the ending point time code variable C to the field of C (n) in the editing point information storage device 12 (Step S312). At this time, as shown in drawing 12, editing point information will be recorded on the editing point information storage device 12. Thus, about the cut (3) shorter than  $T_{accs}$  among the cuts which had four from the first, linear editing is performed at the time of editing point determination, and all data are reproduced by the disk unit 22 for work. Therefore, since it is not necessary to carry out anything at the time of reproduction, the editing point information about a cut (3) is recorded on the editing point information storage device 12, and it is \*\*. Therefore, the editing point information on the next cut (4) is recorded on the field of  $n=3$  in the editing point information storage device 12.

[0038] Operation at the time of the reproduction after edit of the edit equipment concerning the gestalt of this operation is as having been shown in drawing 7 like the gestalt of the 1st operation. At the time of the reproduction at the time of editing about a cut (4) from a cut (1) like the above-mentioned explanation, first, while the disk unit 22 for work has read from D1 point in drawing 3 (b) to D2 point at the time of  $n=1$ , the disk unit 21 for materials seeks to B1 point in drawing 3 (a). And after performing read-out from B1 point to C1 point in the disk unit 21 for materials after  $T_{accs}$  progress, while the disk unit 22 for work has read from D2 point in drawing 3 (b) to D3 point, the disk unit 21 for materials seeks at B-2 point in drawing 3 (a). Furthermore, in the disk unit 21 for materials, read-out from B-2 point to C2 point is performed after  $T_{accs}$  progress. Then, while the disk unit 22 for work has read from D3 point in drawing 8 (b) to D4 point, the disk unit 21 for materials seeks to E4 point in drawing 8 (a). And after  $T_{accs}$  progress, read-out from E4 point to C4 point is performed in the disk unit 21 for materials. That is, seeking to the field of a cut (3) is not performed in the disk unit 21 for materials. About the data of a cut (3), the all are reproduced by the disk unit 22 for work, and will be read from here.

[0039] It can be coped with, when it includes a cut shorter than  $T_{accs}$  according to the edit equipment concerning the gestalt of this operation, as explained above. The composition of others in the gestalt of this operation, operation, and the effect are the same as the gestalt of the 1st operation.

[0040] In addition, although this invention is not limited to the gestalt of each above-mentioned implementation, for example, showed the position of the data on a record medium by the time code with the gestalt of each above-mentioned implementation instead, it may use address information, such as a track number and a sector number.

[0041] Moreover, although the gestalt of each above-mentioned implementation explained the case where an editing-task company determined an editing point, this invention can be applied, when reading editing point information from the equipment connected to the exterior of edit equipment and performing edit and reproduction.

[0042] Moreover, although the gestalt of each above-mentioned implementation explained the example in the case of a combination used as the 1st storage which serves as an optical disk unit and the 2nd storage as a disk unit 21 for materials using the hard disk as a disk unit 22 for work, in the case of the combination of the storage with which access speed differs, this invention can apply a hard disk, semiconductor memory, etc. as a combination of the 1st storage and the 2nd storage.

[0043] Furthermore, it is also possible to use the late storage of access like an optical disk unit or a tape unit as the 2nd storage. It is because these information will be reproduced one by one at the time of reproduction if it records by packing an interval so that it may be set to  $D2=D1+T_{accs}$  as shown in drawing 3 (b) in case data are recorded on the record medium in the 2nd storage.

[0044] Moreover, if record sequential in this way and reproduction are performed, random access does not do the 2nd storage. That is, after record of the head portion of a cut (1) is completed [for example,] at the time of record, or after reproduction of the head portion of a cut (1) is completed at the time of reproduction, a head is already in the head portion of a cut (2), and especially a head does not need to move. Moreover, since it is sequential access, rotational delay can be seemingly abolished by using a read-ahead cache buffer. Therefore, even if it uses late storage of access, such as an optical disk unit and a tape unit, as the 2nd storage, the access time can be shortened enough.

[0045] Moreover, for the reason of having performed additional edit, when the data recorded on the 2nd storage stop being in agreement with reproductive turn, they can shorten the access time at the time of reproduction by rearranging data so that it may become the order of reproduction. After rearrangement of data once reads the data of the portion which rearranges and rearranges them, it is realizable by writing in again. Though such rearrangement is performed, since only the data near the editing point are recorded on the 2nd storage, there is little amount of data and there is little time which rearrangement takes.

[0046]

[Effect of the Invention] As explained above, in case an editing point is determined according to edit equipment according to claim 1 or 2 The data near [in material data] the editing point are reproduced to the 2nd storage from the 1st storage in which the random access which stored material data is possible. at the time of reproduction of the data after edit In case the data near the editing point are reproduced, while reading the data first reproduced by the 2nd storage and considering as reproduction data While having read the data reproduced by the 2nd storage, access to the data which should be reproduced in the 1st storage is performed. Since it was made to use the data which replaced with the data read from the 2nd storage, and was read from the 1st storage as reproduction data after this access was completed Even if the number of editing points increases in material data storage, using the late storage of access, the effect that non-linear editing can be performed is done so, with uttering a

reproduction data transfer rate.

[0047] Moreover, in case the data near [in material data] the editing point are reproduced from the 1st storage to the 2nd storage according to edit equipment according to claim 2. Since an interval is packed and the data near the editing point were recorded on the 2nd storage according to the turn that the data near the editing point are reproduced. Even if it uses the last storage of accesses as the 2nd storage in addition to the above-mentioned effect, the effect that the access time can be shortened enough is demonstrated.

**PRIOR ART**

[Description of the Prior Art] The edit method conventionally performed when editing image data is the method of reproducing only the required portion of a material record medium and reproducing this one by one to another record medium. Generally, such an edit method is called linear editing. On the other hand, the edit method called non-linear editing using the storage in which random access, such as a hard disk drive unit, is possible is being circulated in recent years. In this non-linear editing, by a certain method, the position where the required image in a material record medium is recorded is determined, and this is memorized as editing point information, such as carrying out rapid-traverse reproduction of the material record medium in which random access is possible first. And at the time of reproduction, a desired image program can be acquired by performing random access to a material record medium according to editing point information.

[0003] In linear editing, in order to perform duplicate processing, the working hours which edit takes become longer than the reproduction time of the completed image program at least. On the other hand, in non-linear editing, it is rapid-traverse reproduction etc., and since what is necessary is just to determine even an editing point, the time which an editing task takes can be shortened. Thus, in non-linear editing, efficient work can be done in a short time taking advantage of the advantage of the storage in which random access is possible.

**EFFECT OF THE INVENTION**

---

[Effect of the Invention] As explained above, in case an editing point is determined according to edit equipment according to claim 1 or 2 The data near [ in material data ] the editing point are reproduced to the 2nd storage from the 1st storage in which the random access which stored material data is possible. at the time of reproduction of the data after edit In case the data near the editing point are reproduced, while reading the data first reproduced by the 2nd storage and considering as reproduction data While having read the data reproduced by the 2nd storage, access to the data which should be reproduced in the 1st storage is performed. Since it was made to use the data which replaced with the data read from the 2nd storage, and were read from the 1st storage as reproduction data after this access was completed Even if the number of editing points increases in material data storage, using the late storage of access, the effect that non-linear editing can be performed is done so, without reducing a reproduction data transfer rate.

[0047] Moreover, it is since according to edit equipment according to claim 2 an interval is packed and the data near the editing point were recorded on the 2nd storage according to the turn that the data near the editing point are reproduced, when reproducing the data near [ in material data ] the editing point from the 1st storage to the 2nd storage. Even if it uses the late storage of access as the 2nd storage in addition to the above-mentioned effect, the effect that the access time can be shortened enough is done so.

TECHNICAL PROBLEM

---

[Problem(s) to be Solved by the Invention] By the way, generally in non-linear editing, the disk unit is used as storage in which random access is possible. However, such a disk unit is not the reason in which perfect random access is possible, and requires the time for seeking a head or performing rotational delay on the occasion of access. Especially, in an optical disk unit etc., generally the seek time and rotational delay are large, and these influences cannot be disregarded. For example, in non-linear editing, supposing it connects a different portion in a material record medium for every frame, when reproducing this, seek operation will occur for every frame. Thus, since one seeking must be performed whenever it reads to data of only one frame, the average transfer rate of read-out falls remarkably. If this average transfer rate is less than a required value, a reproduction image will become way piece \*\*\*\*\*. Thus, in the edit equipment which performs non-linear editing, in order to reproduce reproduction data at the transfer rate more than fixed continuously, the number of the editing points in a certain section will be restricted, and it depends for this limiting value on the access time of the storage in which random access is possible.

[0005] Therefore, generally as storage in which the random access in non-linear editing is possible, the quick hard disk drive unit of access etc. is more desirable than the late optical disk unit of access etc. However, on the other hand, an optical disk unit has the advantage of being suitable for recording material data, when using the image recorded outdoors, for example as material data, since the record medium is generally removable. In addition, although the advantage of the both sides of an optical disk unit and a hard disk can be harnessed once it reproduces the material data recorded with the optical disk unit to a hard disk, considering the time of a duplicate, the merit of non-linear editing that it can edit will be lost for a short time.

[0006] this invention was made in view of this trouble, and even if the number of the purpose of editing points increases in material data storage, using the late storage of access, it is to offer the edit equipment which enabled it to perform non-linear editing, without reducing a reproduction data transfer rate.

## MEANS

[Means for Solving the Problem] In the edit equipment for the edit equipment of this invention performing non-linear editing of image data or voice data using the storage in which random access is possible It connects with the 2nd storage for storing the data near [ in the 1st storage in which the random access which stored material data is possible, and material data ] the editing point. In case an editing point is determined, the data near [ in material data ] the editing point are reproduced from the 1st storage to the 2nd storage. at the time of reproduction of the data after edit In case the data near the editing point are reproduced, while reading the data first reproduced by the 2nd storage and considering as reproduction data While having read the data reproduced by the 2nd storage, access to the data which should be reproduced in the 1st storage is performed. After this access is completed, it has the control means which change reproduction data from the data read from the 2nd storage to the data read from the 1st storage.

[0008] With this edit equipment, in case an editing point is determined, the data near [ in material data ] the editing point are reproduced by the 2nd storage from the 1st storage by control means. And at the time of reproduction of the data after edit, by control means, in case the data near the editing point are reproduced The data reproduced by the 2nd storage of introduction are read, and it considers as reproduction data. While the data reproduced by the 2nd storage are read, access to the data which should be reproduced in the 1st storage is performed. After this access is completed, reproduction data are changed from the data read from the 2nd storage to the data read from the 1st storage.

[0009]

[Embodiments of the Invention] Hereafter, the gestalt of operation of this invention is explained in detail with reference to a drawing.

[0010] Drawing 1 is the block diagram showing the structure of a system containing the edit equipment concerning the gestalt of operation of the 1st of this invention. The disk unit 21 for materials as the 1st storage in which the random access which this system was connected to the edit equipment 10 concerning the gestalt of this operation and this edit equipment 10, and stored material data is possible, It connected with edit equipment 10, and it connected with the disk unit 22 for work and the edit equipment 10 as the 2nd storage for storing the data near [ in material data ] the editing point, and has the monitor 23 for displaying a picture. It connected with the disk unit 21 for materials, the disk unit 22 for work, and the monitor 23, and edit equipment 10 is equipped with the control unit 13 as control means which control these while it connects with the editing point information storage device 12, and the user interface 11 and the editing point information storage device 12 for memorizing the information on the editing point in the user interface 11 and material data for performing operation of determining the editing point in material data and it controls these. Control information and data 31 are sent and received between a control unit 13, and the disk unit 21 for materials and the disk unit 22 for work, control information 32 is sent and received between a control unit 13 and a user interface 11, and the editing point information 33 is sent and received between a control unit 13 and the editing point information storage device 12. Moreover, a control unit 13 outputs the reproduction data 34 after edit.

[0011] The user interface 11 contains various kinds of switches, levers, etc. The editing point information recording device 12 is equipment for memorizing time codes, such as a start point of each cut, and an ending point, and consists of a hard disk, semiconductor memory, etc. The control unit 13 has CPU (central processing unit), ROM (read only memory) which stored the program which this CPU performs, and RAM (random access memory) used as a working area.

[0012] Both the disk unit 21 for materials and the disk unit 22 for work shall have the capacity to perform record and reproduction of image data or voice data, and the recorded data shall be managed by the time code. An optical disk unit is used as a disk unit 21 for materials, and a hard disk is used as a disk unit 22 for work.

[0013] The outline of operation of the edit equipment 10 applied to the gestalt of this operation here is explained. Here, it thinks taking the case of the case where use an optical disk unit as a disk unit 21 for materials, and a hard disk is used as a disk unit 22 for work. Since the latency of access of the optical disk unit as a disk unit 21 for materials is covered, when reproducing material data to a hard disk beforehand, it is not necessary to reproduce all the material data to a hard disk. Namely, what is necessary is to reproduce only the data of the period which is equivalent to Taccs from a head, respectively in each cut to connect, if maximum of the time which seeking and rotational delay in an optical disk unit take is set to Taccs. If it sets, in this way, in the case of reproduction of the data after edit The data read from the hard disk are used as reproduction data between Taccs (s) of the head of each cut. In the meantime After it performs access to the data which should be reproduced in an optical disk unit

and the period of Taccs passes. The lateness of access of an optical disk unit is suppliable with changing so that the data which replaced with the data read from a hard disk, and were read from the optical disk unit may be used as reproduction data.

[0014] In order to realize above-mentioned processing, the procedure of reproducing the data of the period of Taccs from the head of each cut from an optical disk unit to a hard disk is required. By the way, a common optical disk unit — setting — Taccs — at most — it is number dozens to 100 milliseconds. On the other hand, an editing-task company determines an editing point, looking at the picture near the editing point by rapid-traverse reproduction etc., after giving near aim, in case an editing point is determined. Since it is the work whose human being does such work, although one editing point is determined, even if short, it takes several seconds. Therefore, though the data of the period of Taccs are reproduced from the head of a cut from an optical disk unit to a hard disk when an editing point is determined, it can carry out abbreviation disregard in time for an editing-task company.

[0015] In case an editing-task company determines an editing point with the edit equipment 10 concerning the form of this operation by the above idea using a user interface 11, a control unit 13 reproduces the data of the period of Taccs from the head of each cut from the disk unit 21 for materials (optical disk unit) to the disk unit 22 for work (hard disk) while making the editing point information storage device 12 memorize the information on an editing point. At the time of reproduction of the data after edit, moreover, a control unit 13 In case the data near the editing point are reproduced, while reading the data first reproduced by the disk unit 22 for work and considering as the reproduction data 34. After performing access to the data which should be reproduced in the disk unit 21 for materials in the meantime and completing this access, control unit 13 uses as the reproduction data 34 the data which replaced with the data read from the disk unit 22 for work, and were read from the disk unit 21 for materials is performed.

[0016] Next, operation of the edit equipment 10 concerning the form of this operation is explained concretely. Here, the maximum Taccs of the access time of this optical disk unit is assumed to be 1 second using the optical disk unit as a disk unit 21 for materials. An optical disk unit is loaded with the optical disk with which material data were recorded. Drawing 3 (a) is a timing chart which shows the position of the cut in the data recorded on the optical disk as a record medium in the disk unit 21 for materials. Hereafter, as shown in drawing 3 (a), the case where edit which extracts cut (1) 41 and cut (2) 42, and connects from the data recorded on the optical disk is performed is considered. In addition, in drawing 3 (a), A1 and C1 express the start point of cut (1) 41, and an ending point, respectively, and A2 and C2 express the start point of cut (2) 42, and the ending point, respectively. Tcut1 expresses the time of cut (1) 41, and Tcut2 expresses the time of cut (2) 42. Moreover, B1 expresses the point after Taccs progress from A1, and B-2 expresses the point after Taccs progress from A2.

[0017] When extracting and connecting cut (1) 41 and cut (2) 42 as mentioned above, with the form of this operation, the data of the portion (it is hereafter described as a head portion.) of the period of Taccs are reproduced from the head of each cut from the disk unit 21 for materials to the disk unit 22 for work. Drawing 3 (b) is a timing chart which shows the data recorded on the disk unit 22 for work. In this drawing 3 (b), a sign 51 expresses the head portion of a cut (1), and the sign 52 expresses the head portion of a cut (2). In the disk unit 22 for work, these head portions 51 and 52 pack an interval, and are recorded. Moreover, in drawing 3 (b), D1 expresses the point of a start of the head portion 51 of a cut (1), D2 expresses the point (it is the same as the point of an end of the head portion 51 of a cut (1).) of a start of the head portion 52 of a cut (2), and D3 expresses the point of an end of the head portion 52 of a cut (2).

[0018] Moreover, below, the time code of each point shown in drawing 3 (a) and (b) explains taking the case of the case where it is the value shown in drawing 4. In addition, with the notation of the time code shown in drawing 4, two digits divided by m, s, and f shall express a part, a second, and a frame, and may be 1 second at 30 frames, respectively.

[0019] Drawing 2 is the flow chart showing operation at the time of edit of the edit equipment 10 concerning the form of this operation. At the time of this edit, a control unit 13 sets initial value of the cut number n to 1 as initial setting first. Moreover, although the copy place time code variable D used in order to show the points D1 and D2 in the disk unit 22 for work and — needs to point out the head of the suitable free area on the record medium in the disk unit 22 for work as initial value, it shall point out D1 point in drawing 3 (b), and sets it to D= 00m00s00 f here (Step S101). Next, a control unit 13 judges whether it is an edit end (Step S102), and, in an edit end, (Y) ends operation at the time of edit. In addition, directions of being an edit end are performed when an editing-task company operates a user interface 11.

[0020] When it is not an edit end (step S102;N) An editing-task company is operating a user interface 11, and minds a control unit 13. Publishing commands (control information), such as reproduction, a rapid traverse, and coma delivery, to the disk unit 21 for materials, displaying the picture of material data on a monitor 23, and looking at this picture. Cut (1) The point of A1 in the head position (a), i.e., drawing 3, of 41 is looked for, and a picture is stopped in the position. And an editing-task company operates start point determination by pushing the predetermined switch in a user interface 11. Therefore, the input of the start point time code variable A is performed, and it is set up with A=A1 (Step S103). In response, as for a control unit 13, the time code in the disk unit 22 for work reproduces the data from A1 point in the section (a), i.e., drawing 3, from A to A+Taccs / in the time code in the disk unit 21 for materials ] t B1 point from the point f D, i.e., D1 point in drawing 3 (b), to a field (Step S104). If the picture is displayed on a monitor 23 with the duplicated data at this time, an editing-task company can check an editing point. Next, a control unit 13 saves the start point time code variable A and the copy place time code

variable D to the field of A (n) in the editing point information storage device 12, and D (n), respectively (Step S105).

[0021] Next, an editing-task company is operating a user interface 11, looks for the ending point of cut (1) 41, i.e., C1 point, and operates ending point determination by pushing a switch etc. Thereby, the input of the ending point time code variable C is performed, and it is set up with  $C=C1$  (Step S106). A control unit 13 saves this ending point time code variable C to the field of C (n) in the editing point information storage device 12 (Step S107). At this time, as shown in drawing 5, editing point information (A (1), C (1), D (1)) will be recorded on the editing point information storage device 12. Next, a control unit 13 increments the cut number n one time (Step S108), equips the next edit with it, and as  $D=D+Taccs$ , as (Step S109) and D point out the free area of the degree in the disk unit 22 for work, i.e., D2 point, it returns to Step S102.

[0022] And an editing-task company looks for and determines a start point A2 and the ending point C2 similarly about cut 2 by performing Step S103 or Step S109 again. Thereby, the start point time code variable A and the ending point time code variable C are set up with  $A=A2$  and  $C=C2$ , respectively. As for a control unit 13, the time code in the disk unit 22 for work reproduces the data from A2 point [ in / the section (a) i.e., drawing 3, from A to  $A+Taccs$  / in the time code in the disk unit 21 for materials ] to B-2 point from the point of D, i.e., D2 point in drawing 3 (b), to a field. A control unit 13 saves each time code variables A, D, and C again to the field of A (n) in the editing point information storage device 12, D (n), and C (n), respectively. At this time, as shown in drawing 6, editing point information will be recorded on the editing point information storage device 12.

[0023] An editing-task company does in this way, and determines an editing point one after another, and the information is recorded on the editing point information storage device 12.

[0024] Drawing 7 is the flow chart showing operation at the time of the reproduction after edit of the edit equipment 10 concerning the form of this operation. At the time of this reproduction, a control unit 13 sets initial value of the cut number n to 1 as initial setting first (Step S201). Next, a control unit 13 judges whether A (n) exists with reference to the editing point information storage device 12 (Step S202). When A (n) does not exist, (N) ends operation at the time of reproduction. When A (n) exists, a control unit 13 reads A (n), C (n), and D (n) from the editing point information storage device 12, and (Y) sets up the time code variables A, S, C, and D with  $A=A(n)$ ,  $S=A(n)+Taccs$ ,  $C=C(n)$ , and  $D=D(n)$ , respectively. In addition, since it is  $n=1$ , they are  $A=A(1)$ ,  $S=A(1)+Taccs$ ,  $C=C(1)$ , and  $D=D(1)$  here. Next, as for a control unit 13, according to these time code variables, a time code [ in / the disk unit 22 for work / for the data of the head portion of a cut (1) ] starts read-out from the point of D, i.e., D1 point in drawing 3 (b), (Step S204). With it, to the disk unit 21 for materials, a control unit 13 publishes an instruction so that a time code may seek at the point of S (Step S205). Here, S points have pointed out the point after Taccs, i.e., B1 point in drawing 3 (a), from A1 point. And after waiting (Step S206) and Taccs pass, only the time of Taccs ends read-out from the disk unit 22 for work (Step S207), and is changed from the disk unit 21 for materials which should already have completed seeking to read-out (Step S208). Then, a control unit 13 increments waiting (Step S209) and Variable n one time (Step S210), returns to Step S202, and moves from the time of C-S passing to regeneration of the next cut.

[0025] A control unit 13 sets up the time code variables A, S, C, and D with  $A=A(2)$ ,  $S=A(2)+Taccs$ ,  $C=C(2)$ , and  $D=D(2)$  with reference to the editing point information storage device 12, respectively. And a control unit 13 starts read-out according to these time code variables from D2 point [ in / the point of D, i.e., drawing 3, (b) / in a time code / in / the disk unit 22 for work / for the data of the head portion of a cut (2) ]. With it, to the disk unit 21 for materials, a control unit 13 publishes an instruction so that a time code may seek at the point of S. Here, S points have pointed out the point after Taccs, i.e., B-2 point in drawing 3 (a), from A2 point. And after Taccs passes, read-out from the disk unit 22 for work is ended, and it changes from the disk unit 21 for materials which should already have completed seeking to read-out.

[0026] Thus, at the time of reproduction, data without a way piece are reproducible with reference to the data of the editing point information storage device 12 by reading data from the disk unit 22 for work, and the disk unit 21 for materials by turns.

[0027] As explained above, in case an editing point is determined according to the edit equipment 10 concerning the gestalt of this operation. The data near [ in material data ] the editing point are reproduced from the disk unit 21 for materials to the disk unit 22 for work. at the time of reproduction of the data after edit. In case the data near the editing point are reproduced, while reading the data first reproduced by the disk unit 22 for work and considering as reproduction data. Access to the data which should be reproduced in the disk unit 21 for materials in the meantime is performed. Since it was made to use the data which replaced with the data read from the disk unit 22 for work, and were read from the disk unit 21 for materials as reproduction data after this access was completed. Even if the number of editing points increases in the disk unit 21 for materials, using the late storage of access, non-linear editing can be performed without reducing a reproduction data transfer rate. Therefore, as a disk unit 21 for materials, even if access is slow, storage with the merit that a record medium is removable or that it is cheap can be used. For example, it is realizable to carry out non-linear editing of the material data recorded with the camera on apparatus videocassette recorder using the optical disk and the magnetic tape as a record medium, and to send them out as it is.

[0028] Next, the editing equipment concerning the gestalt of operation of the 2nd of this invention is explained. Depending on the cut to edit, the time may be shorter than Taccs. Drawing 8 (a) is a timing chart which shows the position of the cut in the data recorded on the disk unit 21 for materials, when it includes such a cut. In addition, in drawing 8 (a), A3 and C3 express the start point of cut (3) 43, and an ending point, respectively, and A4 and C4

xpr ss th start point of cut (4) 44, and th ending point, respectively. Tcut3 expresses the time of cut (3) 43, and Tcut4 expresses th tim of cut (4) 44. Moreover, B3 expresses th point after Taccs progress from A3, and B4 xpresses the point after Taccs progress from A4. Mor over, only Tcopied which mentions E4 later from B4 xpresses th front point. In th xampl shown in drawing 8 (a), the tim Tcut3 of cut (3) 43 is shorter than Taccs. [0029] The edit quipm nt concerning th g stalt of this operation is th xampl which nabl d it to cope with it when above. Th fundamental composition of th dit equipm nt conc rning th gestalt of this op ration is as having been shown in drawing 1 like the gestalt of the 1st operation.

[0030] Drawing 9 is the flow chart showing operation at the time of edit of the edit equipment concerning the gestalt of this operation. In this operation, first, as initial setting, a control unit 13 sets initial value of the cut number n to 1, and sets the copy place time code variable D to 00m00s00 f. Furthermore, a control unit 13 is the flag Small which shows whether the time of a cut is shorter than a predetermined reference value. Cut is set to 0 and the variable Tcopied which shows the sum total time of the cut reproduced as a cut shorter than Taccs within Time Taccs is set to 00m00s00 f (Step S301). Next, a control unit 13 judges whether it is an edit end (Step S302), and, in an edit end, (Y) ends operation at the time of edit.

[0031] When it is not an edit end (step S302;N), an editing-task company is operating a user interface 11, publishing commands (control information), such as reproduction, a rapid traverse, and coma delivery, to the disk unit 21 for materials, displaying the picture of material data on a monitor 23, and looking at this picture through a control unit 13, looks for the head position of a cut (n), and stops a picture in the position. And an editing-task company operates start point determination by pushing the predetermined switch in a user interface 11 etc. Thereby, the input of the start point time code variable A is performed (Step S303). Next, a control unit 13 is Flag Small. Cut judges whether it is 0 (Step S304). Flag Small When Cut is 0, a time code [ in / the disk unit 22 for work / in a time code / in / the disk unit 21 for materials / (Y) / in a control unit 13 ] reproduces the data of the section from A to A+Taccs to the field of D to D+Taccs (Step S305), and time codes A and D are saved to the field of A (n) in the editing point information storage device 12, and D (n), respectively (Step S306) On the other hand, it is Flag Small. When Cut is not 0 (step S304;N), from D+Tcopied, a time code [ in / the disk unit 22 for work / in the time code in the disk unit 21 for materials ] overwrites the field of D+Taccs, and reproduces the data of the section from A to A+Taccs-Tcopied (Step S307), and a control unit 13 overwrites and saves the value of A-Tcopied to the field of A (n) in the editing point information storage device 12 (Step S308).

[0032] If Step S306 or Step S308 is completed, an editing-task company is operating a user interface 11, will look for the ending point of a cut (n), and will operate ending point determination by pushing a switch etc. Thereby, the input of the ending point time code variable C is performed (Step S309). Next, a control unit 13 compares the time from the start point of a cut to an ending point, i.e., C-A, and Taccs-Tcopied, and C-A judges whether it is more than Taccs-Tcopied (Step S310). (Y) sets Variable Tcopied to 00m00s00 f while a control unit 13 sets Flag SmallCut to 0, when C-A is more than Taccs-Tcopied (Step S311). Next, a control unit 13 saves the ending point time code variable C to the field of C (n) in the editing point information storage device 12 (Step S312). Next, a control unit 13 increments the cut number n one time (Step S313), equips the next edit with it, and returns to (St p S314) and Step S302 as D=D+Taccs. On the other hand, when C-A is not more than Taccs-Tcopied (step S310;N), a control unit 13 is Flag Small. While setting Cut to 1, it newly returns to Step S302 by setting to Tcopied the valu which added C-A to Tcopied (Step S315).

[0033] Here, after performing edit of a cut (1) as shown in drawing 3 (a), and a cut (2) to the material data record d on the disk unit 21 for materials, as shown in drawing 8 (a), cut (3) 43 and cut (4) 44 are extracted, and the case where edit which connects is performed is considered. Drawing 8 (b) is a timing chart which shows the data recorded on the disk unit 22 for work at the time of this edit of cut (3) 43 and cut (4) 44. In drawing 8 (b), a sign 53 expresses a cut (3) and the sign 54 expresses the head portion of a cut (4). These cuts (3) In the disk unit 22 for work, the head portions 54 of 53 and a cut (4) pack an interval, and are recorded. Moreover, in drawing 8 (b), D3 xpresses the point of a start of a cut (3), F4 expresses the point of a start of the head portion 54 of a cut (4), and D4 xpresses the point of an end of the head portion 54 of a cut (4). Cut (3) The time Tcut3 of 53 is shorter than Taccs, and the time which doubled cut (3) 53 and the head portion 54 of a cut (4) serves as Taccs. Moreover, below, the time code of each point shown in drawing 8 (a) and (b) explains taking the case of the case where it is the valu shown in drawing 10.

[0034] At the time of the edit about the cut (1) shown in introduction and drawing 3 (a), and a cut (2), it sets to th flow chart shown in drawing 9, and is Flag Small. Since Cut is set to 0 (step S304;Y) and C-A sets it more than Taccs-Tcopied (step S310;Y), operation at the time of edit becomes being the same as that of operation shown in drawing 2, and edit is performed as the gestalt of the 1st operation explained Next, in the case of the edit about a cut (3), they are n= 3, and D= 00m02s00 f. An editing-task company looks for the head position of cut (3) 43, i.e., the point of A3, shown in drawing 8 (a), and operates start point determination by pushing the predetermined switch in a user interface 11 etc. Thereby, the start point time code variable A is set up with A=A3 (Step S303). this tim - flag Small Cut - with 0 - it is (st p S304;Y) - it is - as for a c ntrol unit 13, th tim cod in th disk unit 22 for work reproduces the data from A3 p int [ in / th s ction from A to A+Taccs, i. ., drawing 8, (a) / in th time c de in th disk unit 21 for materials ] to B3 point to the fi ld of D to D+Taccs (Step S305) Under the present circumstances, although invalid data are r produced aft r F4 in drawing 8 (b), this is not tak n as a pr blem. A control unit 13 saves tim c d s A and D furth r to th fi ld of A (3) in th diting p int inf rmati n storag devic 12, and D (3), resp ctiv ly (Step S306). At this tim , as shown in drawing 11, diting point information will b recorded n th diting p int information st rag devic 12.

[0035] Then, an editing-task company looks for the ending point, i.e., C3 point, of cut (3) 43 shown in drawing 8 (a), and operates ending point determination. Thereby, the ending point time code variable C is set up with  $C=C3$ . At this time, a control unit 13 compares the time from the start point of a cut to an ending point, i.e.,  $C-A$ , and  $Taccs-Tcopied$ , and  $C-A$  judges whether it is more than  $Taccs-Tcopied$  (Step S310). Here, when  $C-A$  is more than  $Taccs-Tcopied$ , it is the same as the case of a cut (1) or a cut (2). However, in the cut (3) shown in drawing 8 (a), the time from A3 to C3 is smaller than  $Taccs$ . Moreover,  $Tcopied$  serves as 00m00s00 f at this time. Therefore,  $C-A$  becomes smaller than  $Taccs-Tcopied$  (step S310;N), and a control unit 13 is Flag Small. While setting Cut to 1, the value which added  $C-A$  to  $Tcopied$  is newly set to  $Tcopied$  (Step S315). At this time, since  $Tcopied$  is 00m00s00 f, it serves as  $Tcopied=C-A$ . Furthermore, a control unit 13 does not record the value of the point C, i.e., a time code variable, ending [ cut ] on the editing point information storage device 12 in this case. Moreover, n and a D value are not updated.

[0036] Next, an editing-task company looks for the head position of cut (4) 44, i.e., the point of A4, shown in drawing 8 (a), and operates start point determination by pushing the predetermined switch in a user interface 11 etc. Thereby, the start point time code variable A is set up with  $A=A4$  (Step S303). Next, a control unit 13 is Flag Small. Cut is investigated (Step S304). After the ending point determination of a cut (3), and flag Small Cut is set as 1 (step S304;N) — it is — a control unit 13 The time code in the disk unit 21 for materials The section from A to  $A+Taccs-Tcopied$ , That is, from  $D+Tcopied$ , the time code in the disk unit 22 for work overwrites the field of  $D+Taccs$ , i.e., a field, from F4 point in drawing 8 (b), and reproduces the data from A4 point in drawing 8 (a) to E4 point (Step S307). Moreover, a control unit 13 overwrites the value of  $A-Tcopied$  to the field of A (n) in the editing point information storage device 12, and is saved (Step S308). Although information is recorded on the field of this time A (3) as already shown in drawing 11, it overwrites here and records on it.

[0037] Then, an editing-task company looks for the ending point, i.e., C4 point, of cut (4) 44 shown in drawing 8 (a), and operates ending point determination. Thereby, the ending point time code variable C is set up with  $C=C4$ . this time —  $C-A$  — more than  $Taccs-Tcopied$  — it is (step S310;Y) — a control unit 13 — flag Small Variable  $Tcopied$  is set to 00m00s00 f while setting Cut to 0 (Step S311). Moreover, a control unit 13 saves the ending point time code variable C to the field of C (n) in the editing point information storage device 12 (Step S312). At this time, as shown in drawing 12, editing point information will be recorded on the editing point information storage device 12. Thus, about the cut (3) shorter than  $Taccs$  among the cuts which had four from the first, linear editing is performed at the time of editing point determination, and all data are reproduced by the disk unit 22 for work. Therefore, since it is not necessary to carry out anything at the time of reproduction, the editing point information about a cut (3) is recorded on the editing point information storage device 12, and it is \*\*. Therefore, the editing point information on the next cut (4) is recorded on the field of  $n=3$  in the editing point information storage device 12.

[0038] Operation at the time of the reproduction after edit of the edit equipment concerning the gestalt of this operation is as having been shown in drawing 7 like the gestalt of the 1st operation. At the time of the reproduction at the time of editing about a cut (4) from a cut (1) like the above-mentioned explanation, first, while the disk unit 22 for work has read from D1 point in drawing 3 (b) to D2 point at the time of  $n=1$ , the disk unit 21 for materials seeks to B1 point in drawing 3 (a). And after performing read-out from B1 point to C1 point in the disk unit 21 for materials after  $Taccs$  progress, while the disk unit 22 for work has read from D2 point in drawing 3 (b) to D3 point, the disk unit 21 for materials seeks at B-2 point in drawing 3 (a). Furthermore, in the disk unit 21 for materials, read-out from B-2 point to C2 point is performed after  $Taccs$  progress. Then, while the disk unit 22 for work has read from D3 point in drawing 8 (b) to D4 point, the disk unit 21 for materials seeks to E4 point in drawing 8 (a). And after  $Taccs$  progress, read-out from E4 point to C4 point is performed in the disk unit 21 for materials. That is, seeking to the field of a cut (3) is not performed in the disk unit 21 for materials. About the data of a cut (3), the all are reproduced by the disk unit 22 for work, and will be read from here.

[0039] It can be coped with, when it includes a cut shorter than  $Taccs$  according to the edit equipment concerning the gestalt of this operation, as explained above. The composition of others in the gestalt of this operation, operation, and the effect are the same as the gestalt of the 1st operation.

[0040] In addition, although this invention is not limited to the gestalt of each above-mentioned implementation, for example, showed the position of the data on a record medium by the time code with the gestalt of each above-mentioned implementation instead, it may use address information, such as a track number and a sector number.

[0041] Moreover, although the gestalt of each above-mentioned implementation explained the case where an editing-task company determined an editing point, this invention can be applied, when reading editing point information from the equipment connected to the exterior of edit equipment and performing edit and reproduction.

[0042] Moreover, although the gestalt of each above-mentioned implementation explained the example in the case of a combination used as the 1st storage which serves as an optical disk unit and the 2nd storage as a disk unit 21 for materials using the hard disk as a disk unit 22 for work, in the case of the combination of the storage with which access speed differs, this invention can apply a hard disk, semiconductor memory, etc. as a combination of the 1st storage and the 2nd storage.

[0043] Furthermore, it is also possible to use the latter storage of access like an optical disk unit or a tape unit as the 2nd storage. It is because this information will be reproduced one by one at the time of reproduction if it records by packing an interval so that it may be set to  $D2=D1+Taccs$  as shown in drawing 3 (b) in case data are recorded on the record medium in the 2nd storage.

[0044] Moreover, if reproduction is sequential in this way and reproduction are performed, random access does not do the 2nd storage. That is, after reproduction of the head portion of a cut (1) is completed [ for example, ] at the time of reproduction,

or after reproduction of the head portion of a cut (1) is completed at the time of reproduction, a head is already in the head portion of a cut (2), and specially a head does not need to move. Moreover, since it is sequential access, rotational delay can be seemingly abolished by using a read-ahead cache buffer. Therefore, even if it uses latent storage of access, such as an optical disk unit and a tape unit, as the 2nd storage, the access time can be shortened enough.

[0045] Moreover, for the reason of having performed additional edit, when the data recorded on the 2nd storage stop being in agreement with reproduction turn, they can shorten the access time at the time of reproduction by rearranging data so that it may become the order of reproduction. After rearrangement of data once reads the data of the portion which rearranges and rearranges them, it is realizable by writing in again. Though such rearrangement is performed, since only the data near the editing point are recorded on the 2nd storage, there is little amount of data and there is little time which rearrangement takes.

DESCRIPTION OF DRAWINGS

---

## [Brief Description of the Drawings]

[Drawing 1] It is the block diagram showing the structure of a system containing the edit equipment concerning the gestalt of operation of the 1st of this invention.

[Drawing 2] It is the flow chart showing operation at the time of edit of the edit equipment concerning the gestalt of operation of the 1st of this invention.

[Drawing 3] It is explanatory drawing for explaining operation of the edit equipment concerning the gestalt of operation of the 1st of this invention.

[Drawing 4] It is explanatory drawing showing the time code of each point shown in drawing 3.

[Drawing 5] It is explanatory drawing showing the editing point information recorded on an editing point information storage device in the edit equipment concerning the gestalt of operation of the 1st of this invention.

[Drawing 6] It is explanatory drawing showing the editing point information recorded on an editing point information storage device in the edit equipment concerning the gestalt of operation of the 1st of this invention.

[Drawing 7] It is the flow chart showing operation at the time of the reproduction after edit of the edit equipment concerning the gestalt of operation of the 1st of this invention.

[Drawing 8] It is explanatory drawing for explaining operation of the edit equipment concerning the gestalt of operation of the 2nd of this invention.

[Drawing 9] It is the flow chart showing operation at the time of edit of the edit equipment concerning the gestalt of operation of the 2nd of this invention.

[Drawing 10] It is explanatory drawing showing the time code of each point shown in drawing 8.

[Drawing 11] It is explanatory drawing showing the editing point information recorded on an editing point information storage device in the edit equipment concerning the gestalt of operation of the 2nd of this invention.

[Drawing 12] It is explanatory drawing showing the editing point information recorded on an editing point information storage device in the edit equipment concerning the gestalt of operation of the 2nd of this invention.

(54) 【発明の名称】 編集装置

(57) 【要約】

【課題】 素材データ格納用にアクセスの遅い記憶装置を用い、且つ編集点の数が多くなっても、再生データの転送レートを低下させることなくノンリニア編集を行うことができるようにする。

【解決手段】 制御装置13は、編集点を決定する際に、素材データ中の編集点近傍のデータを、素材用ディスク装置21から作業用ディスク装置22に複製しておき、編集後のデータの再生時には、編集点近傍のデータを再生する際に、始めに作業用ディスク装置22に複製されているデータを読み出して再生データとすると共に、その間に、素材用ディスク装置21において再生すべきデータへのアクセスを行い、このアクセスが完了してから、素材用ディスク装置21から読み出したデータを再生データとする。

## 【特許請求の範囲】

【請求項1】 ランダムアクセスが可能な記憶装置を用いて映像データまたは音声データのノンリニア編集を行うための編集装置において、

素材データを格納したランダムアクセスが可能な第1の記憶装置および素材データ中の編集点近傍のデータを格納するための第2の記憶装置に接続され、編集点を決定する際に、素材データ中の編集点近傍のデータを第1の記憶装置から第2の記憶装置に複製しておき、編集後のデータの再生時には、編集点近傍のデータを再生する際に、始めに第2の記憶装置に複製されているデータを読み出して再生データとすると共に、第2の記憶装置に複製されているデータを読み出している間に、第1の記憶装置において再生すべきデータへのアクセスを行い、このアクセスが完了した後、再生データを、第2の記憶装置から読み出したデータから第1の記憶装置から読み出したデータに切り替える制御手段を備えたことを特徴とする編集装置。

【請求項2】 前記制御手段は、素材データ中の編集点近傍のデータを第1の記憶装置から第2の記憶装置に複製する際に、編集点近傍のデータが再生される順番に従って、間隔を詰めて、編集点近傍のデータを第2の記憶装置に記録することを特徴とする請求項1記載の編集装置。

## 【発明の詳細な説明】

## 【0001】

【発明の属する技術分野】 本発明は、ランダムアクセスが可能な記憶装置を用いて映像データまたは音声データのノンリニア編集を行うための編集装置に関する。

## 【0002】

【従来の技術】 映像データを編集する場合において、従来より行われてきた編集方法は、素材記録媒体の必要部分のみを再生し、これを別の記録媒体に順次複製する方法である。一般に、このような編集方法をリニア編集と呼ぶ。これに対し、近年、ハードディスク装置等のランダムアクセスが可能な記憶装置を用いたノンリニア編集と呼ばれる編集方法が広まりつつある。このノンリニア編集では、まず、ランダムアクセスが可能な素材記録媒体を早送り再生する等、何らかの方法で、素材記録媒体中の必要な映像が記録されている位置を決定し、これを編集点情報として記憶しておく。そして、再生時には、編集点情報に従って素材記録媒体に対してランダムアクセスを行うことで、所望の映像プログラムを得ることができる。

【0003】 リニア編集では、複製処理を行うため、編集に要する作業時間は、少なくとも、完成した映像プログラムの再生時間よりも長くなる。これに対し、ノンリニア編集においては、早送り再生等で、編集点さえ決定してやれば良いため、編集作業に要する時間を短縮することができる。このように、ノンリニア編集において

は、ランダムアクセスが可能な記憶装置の利点を活かして、短時間で効率的な作業を行うことができる。

## 【0004】

【発明が解決しようとする課題】 ところで、一般に、ノンリニア編集においては、ランダムアクセスが可能な記憶装置として、ディスク装置が用いられている。しかしながら、このようなディスク装置は、完全なランダムアクセスが可能なわけではなく、アクセスに際して、ヘッドのシークを行ったり、回転待ちを行ったりするための時間を要する。特に、光ディスク装置等においては、一般にシーク時間や回転待ち時間が大きく、これらの影響を無視できない。例えば、ノンリニア編集において、1フレーム毎に素材記録媒体における異なる部分をつないだとして、これを再生するときには、1フレーム毎にシーク動作が発生することになる。このように、たった1フレームのデータに読み出す毎に、1回のシークを行わなければならないのであるから、読み出しの平均転送レートは著しく低下する。この平均転送レートが、必要な値を下回ると、再生映像は途切れてしまうことになる。このように、ノンリニア編集を行う編集装置においては、再生データを連続して一定以上の転送レートで再生させるためには、ある区間での編集点の数が制限されることになり、この制限値は、ランダムアクセスが可能な記憶装置のアクセス時間に依存する。

【0005】 従って、ノンリニア編集におけるランダムアクセスが可能な記憶装置としては、一般的にアクセスの遅い光ディスク装置等よりも、アクセスの速いハードディスク装置等の方が好ましい。しかし一方、光ディスク装置は、一般に記録媒体がリムーバブルであるから、例えば屋外で収録した映像を素材データとして用いる場合等において、素材データを記録するのに適しているという利点がある。なお、光ディスク装置で収録した素材データを一旦ハードディスクに複製すれば、光ディスク装置とハードディスクの双方の利点を活かすことができるが、複製の時間を考えると、短時間で編集が可能であるというノンリニア編集のメリットが失われてしまう。

【0006】 本発明はかかる問題点に鑑みてなされたもので、その目的は、素材データ格納用にアクセスの遅い記憶装置を用い、且つ編集点の数が多くなっても、再生データの転送レートを低下させることなくノンリニア編集を行うことができるようにした編集装置を提供することにある。

## 【0007】

【課題を解決するための手段】 本発明の編集装置は、ランダムアクセスが可能な記憶装置を用いて映像データまたは音声データのノンリニア編集を行うための編集装置において、素材データを格納したランダムアクセスが可能な第1の記憶装置および素材データ中の編集点近傍のデータを格納するための第2の記憶装置に接続され、編集点を決定する際に、素材データ中の編集点近傍のデ

データを第1の記憶装置から第2の記憶装置に複製しておき、編集後のデータの再生時には、編集点近傍のデータを再生する際に、始めに第2の記憶装置に複製されているデータを読み出して再生データとすると共に、第2の記憶装置に複製されているデータを読み出している間に、第1の記憶装置において再生すべきデータへのアクセスを行い、このアクセスが完了した後、再生データを、第2の記憶装置から読み出したデータから第1の記憶装置から読み出したデータに切り替える制御手段を備えたものである。

【0008】この編集装置では、編集点を決定する際には、制御手段によって、素材データ中の編集点近傍のデータが第1の記憶装置から第2の記憶装置に複製される。そして、編集後のデータの再生時には、制御手段によって、編集点近傍のデータを再生する際に、始めに第2の記憶装置に複製されているデータが読み出されて再生データとされ、第2の記憶装置に複製されているデータが読み出されている間に、第1の記憶装置において再生すべきデータへのアクセスが行われ、このアクセスが完了した後、再生データが、第2の記憶装置から読み出されたデータから第1の記憶装置から読み出されたデータに切り替えられる。

【0009】

【発明の実施の形態】以下、本発明の実施の形態について図面を参照して詳細に説明する。

【0010】図1は本発明の第1の実施の形態に係る編集装置を含むシステムの構成を示すブロック図である。このシステムは、本実施の形態に係る編集装置10と、この編集装置10に接続され、素材データを格納したランダムアクセスが可能な第1の記憶装置としての素材用ディスク装置21と、編集装置10に接続され、素材データ中の編集点近傍のデータを格納するための第2の記憶装置としての作業用ディスク装置22と、編集装置10に接続され、画像を表示するためのモニタ23とを備えている。編集装置10は、素材データにおける編集点を決定する操作を行うためのユーザインタフェース11と、素材データにおける編集点の情報を記憶するための編集点情報記憶装置12と、ユーザインタフェース11および編集点情報記憶装置12に接続され、これらを制御すると共に、素材用ディスク装置21、作業用ディスク装置22およびモニタ23に接続され、これらを制御する制御手段としての制御装置13とを備えている。制御装置13と素材用ディスク装置21、作業用ディスク装置22の間では制御情報およびデータ31が送受され、制御装置13とユーザインタフェース11の間では制御情報32が送受され、制御装置13と編集点情報記憶装置12の間では編集点情報33が送受されるようになっている。また、制御装置13は、編集後の再生データ34を出力するようになっている。

【0011】ユーザインタフェース11は、各種のスィ

ッチやレバー等を含んでいる。編集点情報記憶装置12は、各カットの開始点、終了点等のタイムコードを記憶するための装置であり、ハードディスクや半導体メモリ等で構成される。制御装置13は、CPU（中央処理装置）と、このCPUが実行するプログラム等を格納したROM（リード・オンリ・メモリ）と、ワーキングエリアとなるRAM（ランダム・アクセス・メモリ）とを有している。

【0012】素材用ディスク装置21および作業用ディスク装置22は、共に、映像データまたは音声データの記録および再生を行う能力を持ち、記録されたデータは、タイムコードで管理されるものとする。素材用ディスク装置21としては例えば光ディスク装置が使用され、作業用ディスク装置22としては例えばハードディスクが使用される。

【0013】ここで、本実施の形態に係る編集装置10の動作の概略について説明する。ここでは、素材用ディスク装置21として光ディスク装置を使用し、作業用ディスク装置22としてハードディスクを使用する場合を例にとって考える。素材用ディスク装置21としての光ディスク装置のアクセスの遅さをカバーするために、予め素材データをハードディスクに複製する場合には、素材データの全てをハードディスクに複製する必要はない。すなわち、光ディスク装置におけるシークおよび回転待ちに要する時間の最大値を $T_{accs}$ とすると、つなぎ合わせる各カットにおいて、それぞれ先頭から $T_{accs}$ に相当する期間のデータのみを複製しておけば良い。こうしておけば、編集後のデータの再生の際には、各カットの先頭の $T_{accs}$ の間はハードディスクから読み出したデータを再生データとし、この間に、光ディスク装置において再生すべきデータへのアクセスを行い、 $T_{accs}$ の期間が経過した後は、ハードディスクから読み出すデータに代えて光ディスク装置から読み出したデータを再生データとするように切り替えることで、光ディスク装置のアクセスの遅さを補うことができる。

【0014】上述の処理を実現するには、各カットの先頭から $T_{accs}$ の期間のデータを光ディスク装置からハードディスクに複製するという手順が必要である。ところで、一般的な光ディスク装置においては、 $T_{accs}$ は、たかだか数十から数百m秒である。一方、編集作業者は、編集点を決定する際、早送り再生等により、おおよその見当をつけた後、編集点近傍の画像を見ながら、編集点を決定する。このような作業は、人間が行う作業であるから、一つの編集点を決定するのに、短くても数秒を要する。従って、編集点を決定した際に、カットの先頭から $T_{accs}$ の期間のデータを光ディスク装置からハードディスクに複製したとしても、それは、編集作業者にとって、時間的に略無視できるものである。

【0015】以上の考えにより、本実施の形態に係る編集装置10では、編集作業者がユーザインタフェース1

1を用いて編集点を決定する際に、制御装置13は、編集点の情報を編集点情報記憶装置12に記憶させると共に、各カットの先頭から $T_{\text{accs}}$ の期間のデータを素材用ディスク装置（光ディスク装置）21から作業用ディスク装置（ハードディスク）22に複製しておく。また、編集後のデータの再生時には、制御装置13は、編集点近傍のデータを再生する際に、始めに作業用ディスク装置22に複製されているデータを読み出して再生データ34とすると共に、その間に、素材用ディスク装置21において再生すべきデータへのアクセスを行い、このアクセスが完了した後、作業用ディスク装置22から読み出したデータに代えて素材用ディスク装置21から読み出したデータを再生データ34とするような制御を行う。

【0016】次に、本実施の形態に係る編集装置10の動作について具体的に説明する。ここでは、素材用ディスク装置21としての光ディスク装置を用い、この光ディスク装置のアクセス時間の最大値 $T_{\text{accs}}$ を1秒と仮定する。光ディスク装置には、素材データの収録された光ディスクが装填される。図3(a)は、素材用ディスク装置21における記録媒体としての光ディスクに記録されたデータ中におけるカットの位置を示すタイミングチャートである。以下、図3(a)に示したように、光ディスクに記録されたデータから、カット(1)41とカット(2)42を抜き出して、つなぎ合わせる編集を行う場合について考える。なお、図3(a)において、A1、C1はそれぞれカット(1)41の開始点、終了点を表し、A2、C2はそれぞれカット(2)42の開始点、終了点を表している。 $T_{\text{cut1}}$ はカット(1)41の時間を表し、 $T_{\text{cut2}}$ はカット(2)42の時間を表している。また、B1はA1から $T_{\text{accs}}$ 経過後の点を表し、B2はA2から $T_{\text{accs}}$ 経過後の点を表している。

【0017】上述のようにカット(1)41とカット(2)42を抜き出して、つなぎ合わせる場合、本実施の形態では、各カットの先頭から $T_{\text{accs}}$ の期間の部分（以下、先頭部分と記す。）のデータが、素材用ディスク装置21から作業用ディスク装置22に複製される。図3(b)は、作業用ディスク装置22に記録されたデータを示すタイミングチャートである。この図3(b)において、符号51はカット(1)の先頭部分を表し、符号52はカット(2)の先頭部分を表している。これら先頭部分51、52は、作業用ディスク装置22において間隔を詰めて記録される。また、図3(b)において、D1はカット(1)の先頭部分51の開始の点を表し、D2はカット(2)の先頭部分52の開始の点（カット(1)の先頭部分51の終了の点と同じ。）を表し、D3はカット(2)の先頭部分52の終了の点を表している。

【0018】また、以下では、図3(a)、(b)に示した各点のタイムコードが、図4に示した値である場合

を例にとって説明する。なお、図4に示したタイムコードの表記では、m、s、fで区切られた2桁の数字が、それぞれ、分、秒、フレームを表すものとし、30フレームで1秒とする。

【0019】図2は、本実施の形態に係る編集装置10の編集時の動作を示す流れ図である。この編集時には、まず、制御装置13は、初期設定として、カット番号nの初期値を1とする。また、作業用ディスク装置22における点D1、D2、…を示すために使用される複写先タイムコード変数Dは、初期値として、作業用ディスク装置22における記録媒体上の適当な空き領域の先頭を指している必要があるが、ここでは、図3(b)におけるD1点を指すものとし、 $D=00m00s00f$ とする（ステップS101）。次に、制御装置13は、編集終了か否かを判断し（ステップS102）、編集終了の場合（Y）は、編集時の動作を終了する。なお、編集終了か否かの指示は、編集作業者がユーザインタフェース11を操作することによって行う。

【0020】編集終了ではない場合（ステップS102；N）は、編集作業者は、ユーザインタフェース11を操作することで、制御装置13を介して、素材用ディスク装置21に対して再生、早送り、コマ送りといったコマンド（制御情報）を発行し、モニタ23に素材データの画像を表示させ、この画像を見ながら、カット

(1)41の先頭位置すなわち図3(a)におけるA1の点を探し、その位置で画像を停止させる。そして、編集作業者は、ユーザインタフェース11における所定のスイッチを押す等により、開始点決定の操作を行う。これにより、開始点タイムコード変数Aの入力が行われ、 $A=A1$ と設定される（ステップS103）。これを受けて、制御装置13は、素材用ディスク装置21におけるタイムコードがAから $A+T_{\text{accs}}$ までの区間すなわち図3(a)におけるA1点からB1点までのデータを、作業用ディスク装置22におけるタイムコードがDの点、すなわち図3(b)におけるD1点からの領域に複製する（ステップS104）。このとき、データの複製と共に、その画像をモニタ23に表示すれば、編集作業者は、編集点の確認を行うことができる。次に、制御装置13は、開始点タイムコード変数Aおよび複写先タイムコード変数Dを、それぞれ、編集点情報記憶装置12におけるA(n)、D(n)の領域に保存する（ステップS105）。

【0021】次に、編集作業者は、ユーザインタフェース11を操作することで、カット(1)41の終了点すなわちC1点を探し、スイッチを押す等により、終了点決定の操作を行う。これにより、終了点タイムコード変数Cの入力が行われ、 $C=C1$ と設定される（ステップS106）。制御装置13は、この終了点タイムコード変数Cを、編集点情報記憶装置12におけるC(n)の領域に保存する（ステップS107）。この時点で、編

集点情報記憶装置12には、図5に示すように編集点情報(A(1), C(1), D(1))が記録されることになる。次に、制御装置13は、カット番号nを1インクリメントし(ステップS108)、次の編集に備えて、 $D=D+T_{\text{accs}}$ として(ステップS109)、Dが作業用ディスク装置22における次の空き領域すなわちD2点を指すようにして、ステップS102に戻る。

【0022】そして、再びステップS103ないしステップS109を実行することで、編集作業者は、カット2についても同様に、開始点A2および終了点C2を探し、決定する。これにより、開始点タイムコード変数Aおよび終了点タイムコード変数Cは、それぞれ、 $A=A2$ 、 $C=C2$ と設定される。制御装置13は、素材用ディスク装置21におけるタイムコードがAから $A+T_{\text{accs}}$ までの区間すなわち図3(a)におけるA2点からB2点までのデータを、作業用ディスク装置22におけるタイムコードがDの点、すなわち図3(b)におけるD2点からの領域に複製する。制御装置13は、また、各タイムコード変数A、D、Cを、それぞれ、編集点情報記憶装置12におけるA(n)、D(n)、C(n)の領域に保存する。この時点で、編集点情報記憶装置12には、図6に示すように編集点情報が記録されることになる。

【0023】編集作業者は、このようにして、次々と編集点を決定し、その情報は編集点情報記憶装置12に記録されていく。

【0024】図7は、本実施の形態に係る編集装置10の編集後の再生時の動作を示す流れ図である。この再生時には、まず、制御装置13は、初期設定として、カット番号nの初期値を1とする(ステップS201)。次に、制御装置13は、編集点情報記憶装置12を参照して、A(n)が存在するか否かを判断する(ステップS202)。A(n)が存在しない場合(N)は、再生時の動作を終了する。A(n)が存在する場合(Y)は、制御装置13は、編集点情報記憶装置12から、A(n)、C(n)、D(n)を読み出し、タイムコード変数A、S、C、Dをそれぞれ、 $A=A(n)$ 、 $S=A(n)+T_{\text{accs}}$ 、 $C=C(n)$ 、 $D=D(n)$ と設定する。なお、ここでは、 $n=1$ であるから、 $A=A(1)$ 、 $S=A(1)+T_{\text{accs}}$ 、 $C=C(1)$ 、 $D=D(1)$ である。次に、制御装置13は、これらのタイムコード変数に従って、カット(1)の先頭部分のデータを、作業用ディスク装置22におけるタイムコードがDの点、すなわち図3(b)におけるD1点から読み出しを開始する(ステップS204)。それと共に、制御装置13は、素材用ディスク装置21に対して、タイムコードがSの点にシークを行うように命令を発行する(ステップS205)。ここで、S点は、A1点から $T_{\text{accs}}$ 後の点、すなわち図3(a)におけるB1点を指している。そして、 $T_{\text{accs}}$ の時間だけ待ち(ステップS20

6)、 $T_{\text{accs}}$ が経過した後、作業用ディスク装置22からの読み出しを終了し(ステップS207)、既にシークの完了しているはずの素材用ディスク装置21からの読み出しに切り替える(ステップS208)。その後、制御装置13は、C-Sの時間が経過するのを待ち(ステップS209)、変数nを1インクリメントして(ステップS210)、ステップS202に戻って、次のカットの再生処理に移る。

【0025】制御装置13は、編集点情報記憶装置12を参照して、タイムコード変数A、S、C、Dをそれぞれ、 $A=A(2)$ 、 $S=A(2)+T_{\text{accs}}$ 、 $C=C(2)$ 、 $D=D(2)$ と設定する。そして、制御装置13は、これらのタイムコード変数に従って、カット(2)の先頭部分のデータを、作業用ディスク装置22におけるタイムコードがDの点、すなわち図3(b)におけるD2点から読み出しを開始する。それと共に、制御装置13は、素材用ディスク装置21に対して、タイムコードがSの点にシークを行うように命令を発行する。ここで、S点は、A2点から $T_{\text{accs}}$ 後の点、すなわち図3(a)におけるB2点を指している。そして、 $T_{\text{accs}}$ が経過した後、作業用ディスク装置22からの読み出しを終了し、既にシークの完了しているはずの素材用ディスク装置21からの読み出しに切り替える。

【0026】このように、再生時には、編集点情報記憶装置12のデータを参照して、作業用ディスク装置22と素材用ディスク装置21から交互にデータを読み出していくことで、途切れのないデータを再生することができる。

【0027】以上説明したように本実施の形態に係る編集装置10によれば、編集点を決定する際に、素材データ中の編集点近傍のデータを、素材用ディスク装置21から作業用ディスク装置22に複製しておき、編集後のデータの再生時には、編集点近傍のデータを再生する際に、始めに作業用ディスク装置22に複製されているデータを読み出して再生データとすると共に、その間に、素材用ディスク装置21において再生すべきデータへのアクセスを行い、このアクセスが完了した後、作業用ディスク装置22から読み出したデータに代えて素材用ディスク装置21から読み出したデータを再生データとするようにしたので、素材用ディスク装置21にアクセスの遅い記憶装置を用い、且つ編集点の数が多くなっても、再生データの転送レートを低下させることなくノンリニア編集を行うことができる。従って、素材用ディスク装置21として、アクセスが遅くても、記録媒体がリムーバブルあるいは安価といったメリットのある記憶装置を用いることができる。例えば、光ディスクや磁気テープを記録媒体として用いたカメラ一体型ビデオレコーダで収録した素材データを、ノンリニア編集し、そのまま送り出すといったことを実現することができる。

【0028】次に、本発明の第2の実施の形態に係る編

集装置について説明する。編集するカットによっては、その時間が $T_{accs}$ よりも短い場合もあり得る。図8

(a)は、このようなカットを含む場合において、素材用ディスク装置21に記録されたデータ中におけるカットの位置を示すタイミングチャートである。なお、図8(a)において、A3、C3はそれぞれカット(3)43の開始点、終了点を表し、A4、C4はそれぞれカット(4)44の開始点、終了点を表している。 $T_{cut3}$ はカット(3)43の時間を表し、 $T_{cut4}$ はカット(4)44の時間を表している。また、B3はA3から $T_{accs}$ 経過後の点を表し、B4はA4から $T_{accs}$ 経過後の点を表している。また、E4は、B4から後述する $T_{copied}$ だけ前の点を表している。図8(a)に示した例では、カット(3)43の時間 $T_{cut3}$ が $T_{accs}$ よりも短くなっている。

【0029】本実施の形態に係る編集装置は、上述のような場合に対処することができるようにした例である。本実施の形態に係る編集装置の基本的な構成は、第1の実施の形態と同様に、図1に示した通りである。

【0030】図9は、本実施の形態に係る編集装置の編集時の動作を示す流れ図である。この動作では、まず、制御装置13は、初期設定として、カット番号nの初期値を1とし、複写先タイムコード変数Dを00m00s00fとする。更に、制御装置13は、カットの時間が所定の基準値よりも短いかなを示すフラグSmall Cutを0とし、時間 $T_{accs}$ 内において、 $T_{accs}$ よりも短いカットとして複製されているカットの合計時間を示す変数 $T_{copied}$ を00m00s00fとする(ステップS301)。次に、制御装置13は、編集終了か否かを判断し(ステップS302)、編集終了の場合(Y)は、編集時の動作を終了する。

【0031】編集終了ではない場合(ステップS302;N)は、編集作業者は、ユーザインタフェース11を操作することで、制御装置13を介して、素材用ディスク装置21に対して再生、早送り、コマ送りといったコマンド(制御情報)を発行し、モニタ23に素材データの画像を表示させ、この画像を見ながら、カット(n)の先頭位置を探し、その位置で画像を停止させる。そして、編集作業者は、ユーザインタフェース11における所定のスイッチを押す等により、開始点決定の操作を行う。これにより、開始点タイムコード変数Aの入力が行われる(ステップS303)。次に、制御装置13は、フラグSmall Cutが0か否かを判断する(ステップS304)。フラグSmall Cutが0の場合(Y)は、制御装置13は、素材用ディスク装置21におけるタイムコードがAから $A+T_{accs}$ までの区間のデータを、作業用ディスク装置22におけるタイムコードがDから $D+T_{accs}$ の領域に複製し(ステップS305)、タイムコードA、Dを、それぞれ、編集点情報記憶装置12におけるA(n)、D(n)の領域に

保存する(ステップS306)。一方、フラグSmall Cutが0ではない場合(ステップS304;N)は、制御装置13は、素材用ディスク装置21におけるタイムコードがAから $A+T_{accs}-T_{copied}$ までの区間のデータを、作業用ディスク装置22におけるタイムコードが $D+T_{copied}$ から $D+T_{accs}$ の領域に書き上り複製し(ステップS307)、 $A-T_{copied}$ の値を、編集点情報記憶装置12におけるA(n)の領域に書き上りして保存する(ステップS308)。

【0032】ステップS306またはステップS308が終了したら、編集作業者は、ユーザインタフェース11を操作することで、カット(n)の終了点を探し、スイッチを押す等により、終了点決定の操作を行う。これにより、終了点タイムコード変数Cの入力が行われる(ステップS309)。次に、制御装置13は、カットの開始点から終了点までの時間すなわち $C-A$ と、 $T_{accs}-T_{copied}$ とを比較し、 $C-A$ が $T_{accs}-T_{copied}$ 以上か否かを判断する(ステップS310)。 $C-A$ が $T_{accs}-T_{copied}$ 以上の場合(Y)は、制御装置13は、フラグSmall Cutを0とすると共に、変数 $T_{copied}$ を00m00s00fとする(ステップS311)。次に、制御装置13は、終了点タイムコード変数Cを、編集点情報記憶装置12におけるC(n)の領域に保存する(ステップS312)。次に、制御装置13は、カット番号nを1インクリメントし(ステップS313)、次の編集に備えて、 $D=D+T_{accs}$ として(ステップS314)、ステップS302に戻る。一方、 $C-A$ が $T_{accs}-T_{copied}$ 以上ではない場合(ステップS310;N)は、制御装置13は、フラグSmall Cutを1とすると共に、 $T_{copied}$ に $C-A$ を加えた値を新たに $T_{copied}$ として(ステップS315)、ステップS302に戻る。

【0033】ここで、素材用ディスク装置21に記録された素材データに対して、図3(a)に示したようなカット(1)とカット(2)の編集を行った後に、図8(a)に示したように、カット(3)43とカット

(4)44を抜き出して、つなぎ合わせる編集を行う場合について考える。図8(b)は、このカット(3)43とカット(4)44の編集時に、作業用ディスク装置22に記録されるデータを示すタイミングチャートである。図8(b)において、符号53はカット(3)を表し、符号54はカット(4)の先頭部分を表している。これらカット(3)53とカット(4)の先頭部分54は、作業用ディスク装置22において間隔を詰めて記録される。また、図8(b)において、D3はカット

(3)の開始の点を表し、F4はカット(4)の先頭部分54の開始の点を表し、D4はカット(4)の先頭部分54の終了の点を表している。カット(3)53の時間 $T_{cut3}$ は $T_{accs}$ よりも短く、カット(3)53とカット(4)の先頭部分54とを合わせた時間が $T_{accs}$ とな

っている。また、以下では、図8 (a), (b) に示した各点のタイムコードが、図10に示した値である場合を例にとって説明する。

【0034】始めに、図3 (a) に示したカット (1) とカット (2) についての編集時は、図9に示した流れ図において、フラグSmall Cutは0 (ステップS304; Y)、C-Aは $T_{accs} - T_{copied}$ 以上 (ステップS310; Y) となるため、編集時の動作は、図2に示した動作と同様になり、第1の実施の形態で説明した通りに編集が行われる。次に、カット (3) について

の編集の際には、 $n=3$ 、 $D=00m02s00f$ となっている。編集作業者は、図8 (a) に示したカット (3) 43の先頭位置すなわちA3の点を探し、ユーザインタフェース11における所定のスイッチを押す等により、開始点決定の操作を行う。これにより、開始点タイムコード変数Aは、 $A=A3$ と設定される (ステップS303)。この時点で、フラグSmall Cutは0のままである (ステップS304; Y) ので、制御装置13は、素材用ディスク装置21におけるタイムコードがAから $A+T_{accs}$ までの区間、すなわち図8 (a) におけるA3点からB3点までのデータを、作業用ディスク装置22におけるタイムコードがDから $D+T_{accs}$ の領域に複製する (ステップS305)。この際、図8 (b) におけるF4点以降には無効なデータが複製されるが、これは問題としない。制御装置13は、更に、タイムコードA、Dを、それぞれ編集点情報記憶装置12におけるA (3)、D (3) の領域に保存する (ステップS306)。この時点で、編集点情報記憶装置12には、図11に示すように編集点情報が記録されることになる。

【0035】続いて、編集作業者は、図8 (a) に示したカット (3) 43の終了点すなわちC3点を探し、終了点決定の操作を行う。これにより、終了点タイムコード変数Cは、 $C=C3$ と設定される。このとき、制御装置13は、カットの開始点から終了点までの時間すなわち $C-A$ と、 $T_{accs} - T_{copied}$ とを比較し、 $C-A$ が $T_{accs} - T_{copied}$ 以上か否かを判断する (ステップS310)。ここで、 $C-A$ が $T_{accs} - T_{copied}$ 以上の場合はカット (1) またはカット (2) の場合と同じである。しかし、図8 (a) に示したカット (3) では、A3からC3までの時間は $T_{accs}$ よりも小さい。また、この時点で、 $T_{copied}$ は $00m00s00f$ となっている。従って、 $C-A$ は $T_{accs} - T_{copied}$ よりも小さくなり (ステップS310; N)、制御装置13は、フラグSmall Cutを1とすると共に、 $T_{copied}$ に $C-A$ を加えた値を新たに $T_{copied}$ とする (ステップS315)。この時点では、 $T_{copied}$ は $00m00s00f$ であるので、 $T_{copied}=C-A$ となる。更に、この場合、制御装置13は、カット終了点すなわちタイムコード変数Cの値を、編集点情報記憶装置12に記録しない。また、n

およびDの値を更新しない。

【0036】次に、編集作業者は、図8 (a) に示したカット (4) 44の先頭位置すなわちA4の点を探し、ユーザインタフェース11における所定のスイッチを押す等により、開始点決定の操作を行う。これにより、開始点タイムコード変数Aは、 $A=A4$ と設定される (ステップS303)。次に、制御装置13は、フラグSmall Cutを調べる (ステップS304)。カット (3) の終了点決定後、フラグSmall Cutは1に設定されている (ステップS304; N) ので、制御装置13は、素材用ディスク装置21におけるタイムコードがAから $A+T_{accs} - T_{copied}$ までの区間、すなわち図8 (a) におけるA4点からE4点までのデータを、作業用ディスク装置22におけるタイムコードがDから $D+T_{accs}$ の領域、すなわち図8 (b) におけるF4点からの領域に書き込んで複製する (ステップS307)。また、制御装置13は、 $A - T_{copied}$ の値を、編集点情報記憶装置12におけるA (n) の領域に書き込んで保存する (ステップS308)。このときA (3) の領域には、既に図11に示したように情報が記録されているが、ここに書き込んで記録する。

【0037】続いて、編集作業者は、図8 (a) に示したカット (4) 44の終了点すなわちC4点を探し、終了点決定の操作を行う。これにより、終了点タイムコード変数Cは、 $C=C4$ と設定される。このとき、 $C-A$ が $T_{accs} - T_{copied}$ 以上である (ステップS310; Y) ので、制御装置13は、フラグSmall Cutを0とすると共に、変数 $T_{copied}$ を $00m00s00f$ とする (ステップS311)。また、制御装置13は、終了点タイムコード変数Cを、編集点情報記憶装置12におけるC (n) の領域に保存する (ステップS312)。この時点で、編集点情報記憶装置12には、図12に示すように編集点情報が記録されることになる。このように、元々4つあったカットのうち、 $T_{accs}$ よりも短いカット (3) については、編集点決定時にリニア編集が行われ、全てのデータが作業用ディスク装置22に複製されている。従って、再生時には何もする必要がないので、編集点情報記憶装置12にはカット (3) についての編集点情報は記録されていない。従って、編集点情報記憶装置12における $n=3$ の領域には、次のカット (4) の編集点情報が記録されている。

【0038】本実施の形態に係る編集装置の編集後の再生時の動作は、第1の実施の形態と同様に図7に示した通りである。上記説明のようにカット (1) からカット (4) について編集を行った場合における再生時には、まず、 $n=1$ のとき、作業用ディスク装置22が図3 (b) におけるD1点からD2点までを読み出している間に、素材用ディスク装置21は、図3 (a) におけるB1点にシークを行う。そして、 $T_{accs}$ 経過後に、素材用ディスク装置21においてB1点からC1点までの説

み出しを行った後、作業用ディスク装置 2 2 が図 3

(b) における D 2 点から D 3 点までを読み出している間に、素材用ディスク装置 2 1 は、図 3 (a) における B 2 点にシークを行う。更に、 $T_{\text{accs}}$  経過後に、素材用ディスク装置 2 1 において B 2 点から C 2 点までの読み出しを行う。続いて、作業用ディスク装置 2 2 が図 8

(b) における D 3 点から D 4 点までを読み出している間に、素材用ディスク装置 2 1 は、図 8 (a) における E 4 点にシークを行う。それから  $T_{\text{accs}}$  経過後に、素材用ディスク装置 2 1 において E 4 点から C 4 点までの読み出しを行う。すなわち、素材用ディスク装置 2 1 では、カット (3) の領域へのシークは行わない。カット (3) のデータについては、その全てが作業用ディスク装置 2 2 に複製されており、ここから読み出されることになる。

【0039】以上説明したように、本実施の形態に係る編集装置によれば、 $T_{\text{accs}}$  よりも短いカットを含む場合にも対処することができる。本実施の形態におけるその他の構成、動作および効果は、第 1 の実施の形態と同様である。

【0040】なお、本発明は上記各実施の形態に限定されず、例えば、上記各実施の形態では、記録媒体上のデータの位置を、タイムコードで示すようにしたが、その代わりに、トラック番号やセクタ番号等のアドレス情報を用いても良い。

【0041】また、上記各実施の形態では、編集作業者が編集点を決定する場合について説明したが、本発明は、編集装置の外部に接続された装置から編集点情報を読み込んで、編集、再生を行う場合にも適用することができる。

【0042】また、上記各実施の形態では、第 1 の記憶装置となる素材用ディスク装置 2 1 として光ディスク装置、第 2 の記憶装置となる作業用ディスク装置 2 2 としてハードディスクを用いた組み合わせの場合の例について説明したが、本発明は、第 1 の記憶装置と第 2 の記憶装置の組み合わせとして、ハードディスクと半導体メモリ等、アクセス速度の異なる記憶装置の組み合わせの場合に適用することができる。

【0043】更に、第 2 の記憶装置としては、光ディスク装置やテープ装置等のようにアクセスの遅い記憶装置を用いることも可能である。なぜならば、第 2 の記憶装置における記録媒体にデータを記録する際、図 3 (b) に示したように、 $D2 = D1 + T_{\text{accs}}$  となるように間隔を詰めて記録を行えば、再生時には、これらの情報が順次再生されるからである。

【0044】また、このようにシーケンシャルな記録、再生を行うのであれば、第 2 の記憶装置はランダムアクセスができなくても良い。すなわち、記録時において、例えばカット (1) の先頭部分の記録が終了した後、あるいは再生時においてカット (1) の先頭部分の再生が

終了した後、ヘッドは、既にカット (2) の先頭部分にあり、ヘッドは特に移動する必要がない。また、シーケンシャルなアクセスであるため、先読みキャッシュバッファを用いることで、回転待ち時間を見かけ上無くすることができる。従って、第 2 の記憶装置として光ディスク装置やテープ装置等のアクセスの遅い記憶装置を用いても、アクセス時間を十分短くすることができる。

【0045】また、もし、追加編集を行った等の理由により、第 2 の記憶装置に記録されたデータが、再生の順番と一致しなくなった場合には、再生順となるようにデータの並べ替えを行うことで、再生時のアクセス時間を短縮することができる。データの並べ替えは、例えば、並べ替えを行う部分のデータを一旦読み出し、並べ替えた後に再度書き込むことで実現することができる。このような並べ替えを行ったとしても、第 2 の記憶装置には、編集点近傍のデータしか記録されていないため、データ量は少なく、並べ替えに要する時間は少ない。

【0046】

【発明の効果】以上説明したように請求項 1 または 2 記載の編集装置によれば、編集点を決定する際に、素材データ中の編集点近傍のデータを、素材データを格納したランダムアクセスが可能な第 1 の記憶装置から第 2 の記憶装置に複製しておき、編集後のデータの再生時には、編集点近傍のデータを再生する際に、始めに第 2 の記憶装置に複製されているデータを読み出して再生データとすると共に、第 2 の記憶装置に複製されているデータを読み出している間に、第 1 の記憶装置において再生すべきデータへのアクセスを行い、このアクセスが完了した後、第 2 の記憶装置から読み出したデータに代えて第 1 の記憶装置から読み出したデータを再生データとするようにしたので、素材データ格納用にアクセスの遅い記憶装置を用い、且つ編集点の数が多くなっても、再生データの転送レートを低下させることなくノンリニア編集を行うことができるという効果を奏する。

【0047】また、請求項 2 記載の編集装置によれば、素材データ中の編集点近傍のデータを第 1 の記憶装置から第 2 の記憶装置に複製する際に、編集点近傍のデータが再生される順番に従って、間隔を詰めて、編集点近傍のデータを第 2 の記憶装置に記録するようにしたので、上記効果に加え、第 2 の記憶装置としてアクセスの遅い記憶装置を用いても、アクセス時間を十分短くすることができるという効果を奏する。
